A frame of studies by W. Wainwright, jun., on home prepared gelatine plates (21) will repay examination: some pleasant landscape bits, groups of cows and pigs, are very good; as are the Italian views of Mr. Andrew Pringle. These are instructive also. It has been customary to regard landscapes produced by the photographers of Italy and other places in the south of Europe as lacking in atmosphere, softness, and breadth, because of the hard, brilliant light and absence of suitable atmospheric conditions belonging to the country. But Mr. Pringle has mastered this difficulty so far as it may have existed. There is no hardness, no chalky lights, and sticking-plaster shadows: all is harmonious, and full of tone and colour. Mr. B. King's instantaneous effects on gelatine plates are very good. The rarely beautiful landscapes exhibited by Mr. Payne Jennings very plainly show that process is quite subsidiary to person. The photographer, and not his method, determines the quality of the picture. Here are prints from wet plate negatives, and prints from gelatine negatives, side by side, and all possessing the same especial quality of luminiumness which distinguishes Mr. Jennings' work. These pictures have received from the jury "honourable mention"; the wonder to us is how they escaped a medal!

Col. Stuart Wortley has often contributed grand instantaneous effects of sea and cloud. This year he has exceeded himself. His large studies are marvellously fine. What a pity that the effect is marred by a polygonal aperture in the mount in place of a simple circle! A series of smaller circular pictures, entitled the "Dogs of Scilly and their Prey," presents some marvellous effects of instantaneity, in breaking waves, throwing up clouds of spray, rendered with a degree of crispness which is as effective as wonderful. The series well earn the medal they have received.

Wet collodion still holds its own. Nothing could well exceed in beauty the charming series of Welsh and Devonshire scenes sent by Mr. W. Bedford, in which he maintains—it would be difficult to transcend—the traditions of his father. The "Devonshire Lane" (48) to which the medal is awarded, is a singularly fine landscape composition, combining vigour with tenderness and delicacy, and fine atmospheric softness with great brilliancy. A series of frames by James Valentine and Sons, of Dundee, contains some very interesting pictures. The studies of sea subjects in No. 28 are very good; there is a boldness of style and vigour of treatment which are very effective. Of Mr. S. G. Payne's instantaneous landscapes on 12 by 10 plates we have already spoken. It is very difficult to say which is best; perhaps "Carrying and Gleaning" (68) is one of the most effective. But in all the skill and taste in selecting and securing the grouping, and the photographic skill in rendering so perfectly are beyond praise. The landscapes of Mr. Vernon Heath are, as they always are, very perfect, well chosen, well lighted, and singularly perfect in treatment and manipulation. A frame of veteran trees from Burnham Beeches present some noble pictures. An admirable rendering of Stoke Pogis Church, rendered immortal as the scene of Gray's "Elegy," from which the curfew tolls the knell of parting day, is a fine as well as an interesting picture. Mr. Heath's contributions have obtained from the jury honourable mention.

Our list of noticeable landscapes is by no means exhausted; but as we must return to the subject we leave them for the present to fulfil our promise of last week as regards giving the name of contributors receiving honourable mention. They are as follows:—Messrs. Vernon Heath, B. King, James Valentine and Sons, W. J. A.

Grant, Henry Dixon, Albert Clout, C. Bossetti, H. P. Robison, W. Gillard, W. Huggins, D.C.L., H. S. Mendelssohn, Alfred S. Fisk, W. Willis, Jun., Nitikin, Brandel. We cannot but feel extreme regret that whilst untrammelled by conditions as to number, the jury did not feel at liberty to award medals to several here distinguished by honourable mention. They are all well worthy of distinction; but there are special conditions, in some cases, which take the cases out of the ordinary run of merit. In the case of Mr. Willis, he has not only exhibited fine specimens, but he has enriched the art by the invention of a new process, new in principle, and excellent in result, with the added advantage of probable permanency. Invention, it is fortunate, is not dependent upon such encouragement, otherwise we should feel that this was distinct repression in place of encouragement. Mr. Grant's Arctic photographs are distinctive in their excellency, under peculiarly trying conditions, and were well worthy of a medal. Mr. Robinson's grand example of *chiaroscuro* is a rare photographic triumph in artistic work. It is not, perhaps, a pretty picture. The model might have been attractively beautiful, and the cottage interior accessories rare and picturesque; but this was not the aim of the picture. It seems to us an attempt in photographic monochrome to produce the curious contrast of two lights, firelight and declining daylight, and to secure breadth and keeping at the same time, and this is effected with a painter's skill. And the artist who takes photography a step beyond its usual boundaries deserves, it seems to us, especial recognition. But to the recipient of so many gold and silver medals, a bronze more or less can matter little, beyond the disappointment in not finding the aim of his work recognized. Possibly with a full and complete jury this might have been otherwise. On the whole, the awards will give satisfaction—a rare circumstance, and one to be thankful for.

REMOVING HYPO FROM PRINTS.

A CORRESPONDENT in another column suggests a very simple and, probably, efficient method of removing the hyposulphite from silver prints. A solution of hyposulphite of soda, or of any other salt, is necessarily of greater density than water, and will naturally sink by its own gravity, so as to form a distinct stratum underneath the water. It follows that in the ordinary method of washing prints by leaving them soaking in a dish of water they are, in reality, left lying at the bottom soaking in a weak solution of hyposulphite, in which it may often happen the initial steps of fading are originated. Mr. Higgin suggests that the prints shall be confined to the upper strata of water, the heavier solution of hyposulphite being, as it is, gradually soaked from them suffered to sink, and so be carried away from the prints.

In some washing machines, we have seen, this principle has been partially recognized, as the prints have been laid on a net-work of gutta-percha suspended within the washing trough. But the trough has been made to rock so as to keep the prints and water in motion, and this rocking motion would continually stir up the hypo solution to mix with the mass of water, and so defeat the end. To carry out the principle described by Mr. Higgin, it is necessary that the vessel should be kept quite still, so that the hypo solution may rest at the bottom undisturbed.

FRENCH CORRESPONDENCE.

PHOTOGRAPHY AT THE NATIONAL LIBRARY OF FRANCE—ILLUSTRATED WORKS AND PHOTOGRAPHIC LITERATURE—BANQUET OF THE CHAMBRE SYNDICALE OF PARIS.

Photography at the National Library of France.—When one of the great offices of State organizes a photographic department we have every reason to express our satisfac-

tion, and are bound to take note of this proof of the appreciation in which are held the services rendered by our art. The National Library of France, whose reconstruction and re-arrangement have lately been completed, is about to add to its surroundings a properly-fitted photographic studio. In compliance with the demands of our time, and to meet the requirements of the various interests concerned, the French Department of Fine Arts had given permission for the photographic reproduction of all the works and objects to be found in its valuable collections; but it was found in practice that the enjoyment by the public of this official privilege was accompanied by many inconveniences which it is now desired to put an end to. Rare engravings, costly books, ancient artistic bindings, historical medals, unique coins, old cameos, are not always properly handled by photographic operators, among whom, though there are many who understand the value of the objects confided to them for copying, there are others who do not exhibit the necessary care in dealing with them. In this way important historical and archaeological records often run the risk of damage through unskilful handling. Moreover, it is scarcely prudent to entrust to everyone who presents himself precious works of art, the property of the nation, and guarded for ages with the greatest and most jealous care. It became, therefore, necessary to discover some means of combining the required security of custody, the duties of the state, and the interests of the public; from whom, notwithstanding the acknowledgment of certain abuses, it was impossible to withdraw privileges as wise as they are liberal. With this laudable object it was determined to establish within the precincts of the National Library itself a photographic department properly equipped and managed. To organise such a department has been found sufficiently difficult. Should it be left to the authorities of the library to take the negative, so that only a copy of the object to be photographed would be delivered to the public? In that case the photographer would have only to make a reproduction—which is always a disadvantage—or else he would be compelled to accept a negative, produced officially, under conditions which would often not be those that he would have himself selected. Would it be right to extend the liberty of action so far as to allow the photographer to take his negative in the way he himself thought best? This, of course, would be the arrangement most wished for by the public; but in that case the operator, often an uneducated assistant, not possessing a proper acquaintance with the value of works of art, would be called on himself to place in position the object that he intended to photograph. These questions have been examined from all sides and without venturing to assert that they have been definitely settled, I am in a position to state that they are on the point of being so, and that they will be set at rest by the promulgation of a set of rules more elastic than those which are temporarily in force in the interest of the public service. As it seems to me, the interests of all concerned would be sufficiently protected by an arrangement permitting the photographer to point out to one of the library curators, told off for the purpose, the position in which he wishes to have placed the object that he is about to photograph; he should enter into a complete understanding with this official, and after the position is completely arranged to his liking, he should be at liberty to take his photograph in his own way. A dark room would, of course, be placed at his disposal by the authorities, where he could develop the image, and if the latter were not satisfactory, he would be allowed to recommence his labour until he had attained the required result. In this way the object would not have left the charge or custody of the official authorities, and every one would be acquainted with and responsible for the special duties required of him.

Publication of a Work Illustrated by Photo-Engraving, and of a Practical Text-Book on Phototypie.—The application of

photography to the illustration of books is now an established fact, independent of every influence except that of the arrangements necessary to keep order in its manipulation on a large scale. All the world of literature and science experiences a lively satisfaction at observing the daily increasing importance of the effective—one might almost say indispensable—series that photography is able to render to artistic and scientific publications. Very recently the Director at the Museum at Lyons has published a most interesting work on the Fine Art Exhibition which was held at Lyons in 1877. This work constitutes, in fact, a descriptive analytical selected catalogue, with reproductions in photo-engraving, of the art objects shown at this exhibition, one of the most artistic and completest of its kind that have been organised of late years. Some of the most valuable of art treasures were exhibited there; among them the "Martyrdom of St. Sebastian," by Raphael, pictures by Ruysdael, Vandyk, Adriaen Branwer, Miervelt, Grenze, Delacroix and Regnault; statuettes by Tanagra, the Vienna Venus, since added to the Louvre collection, ivories and carvings of the highest order of merit, tapestries of especial beauty, superb enamels, carved furniture of the renaissance, and metal work of the Gothic period. The selection is issued in the form of an album, and is in itself a real work of art which cannot fail to be of great service to art students. The plates in photo-engraving have been executed by the Dujardin process in a style of great excellence. It is much to be wished that all art exhibitions could be perpetuated by the same means, and thanks to the labours of our phototypographers, Goupil, Lemercier, Thiel, and Dujardin, we are making successful progress in that direction. A work of this description prolongs, so to say, an exhibition indefinitely, to the great advantage of the history of art, which is thus able to preserve more than the simple date of the event, as well as of art education, which can continually profit by it. While on this topic I may be allowed also to call attention to the publication (after some delay, due entirely to unforeseen circumstances) by my esteemed colleague, M. Leon Vidal, of his new "Practical Treatise on Phototypie," which I believe will be found to be a most serviceable work. Phototypie is destined in my opinion to popularize all the productions of photography, and to serve the different branches of art and science in the character of a powerful engine for spreading all over the world intelligence and information which must develop the cultivation of the human intellect. M. Vidal may be unequivocally congratulated on the project that he has devised of making known all the processes for positive printing by phototypie, whose future seems to be unbounded; and not less in the wonderful skill with which he has put his idea into practice. His book will meet a real want, and I recommend strongly all the photographic journals, without distinction of nationality, to reproduce extracts from it. The progress of photography and of the arts depending on it will never be impeded by the barriers which separate one people from another, if only those who really desire to promote it will abstain from raising the new hindrances of national jealousy and enmity; these passions have absolutely no place in a question relating to the independent practice of an art or of a profession which is common to the whole world.

Banquet of the Chambre Syndicale de la Photographie at Paris.—At the banquet of the *Chambre Syndicale de Paris* held on the 6th of the present month, the progress of photography seemed also to be the chief subject of conversation among the members. All the proposals made had for their object the increasing of the number of members of the association, and the extension of its influence, so that it might be able successfully to promote the prosperity and the interest of the photographic profession. In the discussion following the banquet the question was raised of finding some means of giving fresh life to the association, but there seemed to be a difference of opinion on matters of detail; in fact, a general fear was expressed that some of the measures proposed departed too much from the line

of conduct laid down for the *Chambre Syndicale* by the powers conferred on it by its constitution. These powers, however, are not exactly settled, since in France, contrary to what is the custom in other countries, associated institutions of the nature of *Chambres Syndicales* possess no official character. Even in Paris they are dependent on the authorities of a private enterprise, by whom, in return for payment, they are furnished with a locality and means for holding their meetings. It is to be hoped, however, that the banquet will produce good results. Unfortunately, it was attended by a very small number of guests, owing to a paragraph inserted in the circular of invitation, compelling any subscribers who wished to speak at the banquet to submit their toasts beforehand to the convening committee for approval. This regulation in many instances offended sentiments of liberty and good fellowship, and was the cause of many abstentions. Nevertheless, those who absented themselves need not have been alarmed, as in the end perfect freedom of speech was accorded to every one.

KARL VERSNAEYEN.

PHOTOGRAPHS OF BEAUTIFUL WOMEN.

PHOTOGRAPHERS and the public generally are familiar with the fact that photographed portraits of several beautiful women, moving in good circles in English society, have had a somewhat extensive sale for some time past. How portraits of private persons got into circulation we cannot say, but a newspaper writer has recently professed to explain the matter, intimating that some of these ladies voluntarily issue these photographs, and make a market of their pictured charms. As the story told seems to have been false, an action for libel has very naturally followed, the report of which, as published in the *Times*, may be specially interesting to photographers. We give it in a slightly condensed form:—

At the Guildhall, on Saturday, Adolphus Rosenberg, of 4, Ludgate Circus Buildings, the publisher of *Town Talk*, was brought up on a warrant before Alderman Staples and Sir Thomas Dakin charged with publishing a defamatory libel of and concerning Mrs. Cornwallis West. Mr. Edward Lewis prosecuted, and Mr. Beard appeared for Rosenberg.

Mr. Lewis said he appeared to prosecute the defendant on behalf of Mr. Cornwallis West, of 49, Eaton Place, and Ruthin Castle, Denbigh, of which county he is the Lord Lieutenant. The defendant was the publisher of a paper called *Town Talk*. Of the character of that paper he need say nothing there, but the libel was of such a filthy and foul character that he wished publicly to send the contradiction forth to the world. He desired to say publicly that every single person who was engaged in the printing, publishing, and making up of the paper, and those who assisted in disseminating the libels, would be proceeded against, and the law would be put in force against them with the utmost rigour. Every single statement or particle of statement contained in the lengthy article he was about to read to them was from beginning to end an infamous lie. There was not only not a particle of truth in it, but there was not the semblance nor the shadow of a fact of any kind upon which that monstrous superstructure of lies had been built. The article was headed 'Mrs. Cornwallis West at Home.' The writer proceeded:—

"It is an undoubted fact that the most aristocratic portion of English society has done more towards making our British higher classes a byword for scandal and scoffing than all the efforts of demagogues and republicans put together. To think that a lady of exalted position should find it worth her while to be photographed for sale is a disgrace to the upper ten thousand, and I trust that the rumour is true that Her Most Gracious Majesty has issued an express wish that this traffic in the likenesses of photographic beauties shall be discontinued. It certainly does not make foreign countries and critics think much of our Lord Lieutenant of Denbigh that, for the sake of gratifying his wife's stupid vanity, and realizing a few pounds per annum, he allows that lady's photo to be exposed for sale at a price from one penny to two shillings and sixpence. Mr. Cornwallis West is a dignitary, who ought certainly to uphold his position as a Lord Lieutenant, and he does not do so when he allows Mrs.

West, the bone of his bone, and the flesh of his flesh, to make the public exhibition of herself that is daily seen in our fashionable shop windows. When an official of high rank permits his wife to display her charms side by side with the portraiture of half-naked actresses and entirely naked Zulu women, he can have but little respect for himself, for her, or for his position.

"Mrs. West lives in the neighbourhood of Eaton Square, in the region known as Pimlico. At the back of the house is a yard, and in this yard are four corners, and in each corner is a photographic studio; in addition to this there is a glass house on the roof, and fifteen dark rooms on the various landings. It is almost impossible to conceive the labour gone through by Mrs. West in the course of a day. About seven o'clock she takes her breakfast, and after reading *Town Talk* and the *Denbigh Daily*, sent her by Mr. W., she proceeds to her extensive wardrobe, and attires herself ready for the first photographic artist who happens to call. Jane—that is the name of her lady's-maid—has strict orders to state that she is not at home to any one except Fradelle and Marshall or the Stereoscopic Company's young man. When either of these parties arrive they are taken into the front parlour and treated to a glass of something short, and conducted afterwards into one or other of the photographic studios. Sometimes each of all five of these rooms contains an operator at the same time, and Mrs. West rushes from one to the other in various costumes with a rapidity that is something marvellous. Her changes of costume are so quickly manipulated that any quick-change artist is completely 'out of the hunt.' Now in blue satin, now in red, then in green, nextly in white—she seems to be a kind of human female chameleon. Sometimes she is taken with a grin, occasionally with a leer; at times with a devotional aspect, and at other times quite 't'other.' Having been taken about fifteen times in as many new positions, the photographers are dismissed for a time, and Mrs. West rests after her laborious exertions, and having partaken of a light luncheon of hard boiled eggs, she dresses herself, and the brougham or victoria (according to the state of the weather) is brought round to the door, and she drives round to the various shops to collect her commission on the cartes-de-visite and the cabinets that have been sold during the previous day. I do not vouch for the truth of the statement, but I am informed that this little commission amounts to thousands annually; and the joke of the whole thing is that these pictures are purchased principally by 'cads,' who show the likenesses about to their friends, and oftentimes boast that they were given to them by Mrs. West herself; and I cannot say that I in any way pity the lady, for she lays herself open to this sort of insult.

"A woman must have come indeed to a low estimate of her womanhood when her vanity permits her to do this sort of thing. If Mrs. Cornwallis West had done any one act to make herself known as a good or great woman, if she were a heroine, or even a murderess, there would be some excuse in the traffic. When actresses get themselves taken it is excusable; when—are sold from the windows of our fashionable shops, it is understood that they are as shameless as they are goodlooking; but when a woman of position, such as Mrs. West, classes herself with the latter, she has only herself to blame if the casual purchaser considers her to be in 'the same street.' After having received her commission she returns home again to assume fresh positions, put on other costumes, and be taken backwards, full-face, and in profile.

"One of Mrs. West's greatest troubles is the fact that she is so out-photographed by Mrs. Langtry; and the knowledge that Mrs. L. has been illustrated by George Purkess in the *Police News* has excited Mrs. West to the very greatest extent. I have heard that George has been offered an enormous sum by Mrs. W. to enshrine her likeness among his roll of famous men and women, but I am afraid that he has been bribed by the other photographic professional beauty to give her the monopoly of appearing in his charming paper. I daresay that all my readers have heard the following quotation from the works of an unknown poet:—

"What is your fortune, my pretty maid?

"My face is my fortune, sir, she said."

This was evidently written in a prophetic vein, and the author must have had the Wests and the Langtrys in his eye. I am particularly requested to state that Mrs. West is not in way related to Billy West, the stump orator. His wife's name is Emma, not Cornwallis. Mrs. Cornwallis West has a quantity of pets, all of which are appropriately named after the articles used in the trade in which she has embarked. For instance, her

collie dog is named 'Collieodion, her cat is called Iodide of Potassium, while the parrot is known as Camera Poll. The lady is so far devoted to the photographic art that after diuner she retires to her chamber, and has a silver bath preparatory to proceeding to the opera or one of the many aristocratic gatherings at which she is the reigning bello. Returning home late at night, she is met by one of the young men from Mr. Mayall's, and is taken in evening costume by magnesium light, after which she retires to rest."

Mr. Lewis went on to say.—When Mr. West saw the libel his first impulse was to go to the office and administer condign punishment, but on reflection he determined to drag the defendant before a court of justice as a criminal. When somebody waited on the defendant in reference to the libel he rubbed his hands in exultation, and said that he hoped they would bring an action against him, and half a dozen actions. He (Mr. Lewis) hoped that when the disgusting character of that wretched rag was known the wave of public indignation would surge in and sweep away the paper and all the parties connected with it, never to rise again. He would now call Mr. West, who would give an emphatic denial to the libel, and then he should ask for a remand.

Mr. William Cornwallis West said.—My town residence is 49, Eaton Place. I am Lord Lieutenant of the county of Donbigh. On Wednesday last, the 8th inst., I purchased a copy of *Town Talk* of the 4th of October. It appears by the imprint to be printed by A. Rosenberg. I have read the article "Mrs. Cornwallis West at home." That lady is my wife. Beyond the statements that I live at 49, Eaton Place, and that I am Lord Lieutenant of Denbigh, there is not one word of truth in it. So far from allowing my wife's photographs to be sold, I and my solicitor have taken every step to prevent that being done. There are no photographic studios in my house. There is not a glass roof to it. I never had a photographic apparatus in my house to my knowledge.

Mr. Williams then stated that for a long time past a series of libels had appeared in *Town Talk* referring to Mr. and Mrs. Langtry, who lived at 17, Norfolk Street, Park Lane. The libels that had been published against them were the most wicked, foul, and venomous tissue of falsehoods that had ever been put into print.

Extracts were read from *Town Talk* alleging that an application for divorce had been made by Mr. Langtry, and then withdrawn. Mr. Langtry said there was no truth in the assertion.

Ultimately the defendant was remanded until Wednesday. Two sureties in £500 each and himself in £1,000, in each case, were asked for, but were not forthcoming, and the defendant was removed to the cells.

Correspondence.

REMOVING HYPOSULPHITE FROM PRINTS.

SIR,—Allow me to bring before the professors of the "black art" the following cure for their troubles about getting hypo out of their prints. The remedy (the invention of Dr. Mastermann) is so ridiculously simple that one only wonders it was never found out before.

A solution of hypo, being of greater specific gravity than water, will naturally fall to the bottom, and remain there. On this fact the system is based. Make a sieve out of a wooden hoop (a cheese box top is as good as anything) by stringing cotton or linen thread from tacks or wire loops from side to side at intervals of one and a-half or two inches apart. Upon this sieve place the prints to be washed; place prints and sieve on the top of a vessel or bath big enough to receive them. The sieve will float an inch or two above the water, and the paper will lie on the network of the sieve. That is all. The prints left for twelve or twenty-four hours will wash themselves, and the most delicate test will fail to find any hypo in the paper after that period.

Be careful not to shake the bath, which should be of rain or distilled water, as the hyposulphite which has left the prints is lying at the bottom of the vessel.—Your obedient servant,
G. W. HIGGIN.

PHOSPHORESCENT SULPHIDE OF CALCIUM.

DEAR SIR,—It may interest your readers to know that the phosphorescent sulphide of calcium with which we have lately become familiar in this country is exceedingly rich in actinic rays after exposure to light. A strip of paper coated with the sulphide and exposed to sunlight for five minutes, when brought into the dark room acted as quickly and energetically against a Swan gelatine plate as an ordinary gas fish-tail burner. An exposure of thirty seconds face to face with the sensitive gelatine film produced a deep image.

Niece St. Victor, it may be remembered, proved that white earthenware and other similar objects absorbed light and were capable of radiating it again in a similar manner upon a sensitive photographic film, but the action in the case of the phosphorescent sulphide of calcium is of course very much greater. I hear that it is the intention of a French firm to manufacture lanterns covered with this material which will shine by means of light that has been previously absorbed. So sanguine are many as to its phosphorescent capacity, that it is to be tried for illuminating coal mines.

Swift's *Savan* in the Island of Laputa who occupied his time in extracting rays of light from cucumbers would have found plenty to do in manipulating this new form of sulphide of calcium.—Faithfully yours,

H. BADEN PRITCHARD,

General Photographic Establishment of the War Department,
October 15th.

Proceedings of Societies.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE Annual Meeting of the above took place at the Museum, Queen's Road, on Wednesday, October 1st, Mr. T. DAVEY in the chair.

The minutes of the previous meeting having been passed, Mr. Munro was elected an ordinary member of the Association.

The HON. SECRETARY then read a letter of resignation from Mr. P. J. Worsley, one of the Vice-Presidents, who regretted having to take this action on account of his inability to find time for filling the post to his satisfaction.

Regret was expressed at the loss of one so universally esteemed, and it was decided to request Mr. Worsley to become an hon. member.

Mr. H. A. H. DANIEL then suggested that probably Col. Biggs would accept the vacant Vice-Presidentship.

Mr. E. BRIGHTMAN proposed, and Mr. G. A. POWELL seconded, the resolution that Col. Biggs be invited to accept the post of Vice-President rendered vacant by Mr. Worsley's resignation.

The HON. SECRETARY then read the Annual Report as follows.

Annual Report.

"The time has again arrived for your Council to present the report for the past year, which it does with a certain amount of pleasure. Some valuable members have been elected during the past session, and although the number of new members has not reached that of last year, still the total strength of the Association more than keeps up, which must be a subject for congratulation.

"The following papers and communications have been contributed by various members:—'Notes on Staining Gelatine Films,' by Lieut. Lysaght; 'Exhibition of Woodbury and other Lantern Slides,' by various members; 'On Causes of Insolubility of Carbon Tissue,' by Mr. E. Brightman; 'Lautern Exhibition,' by various members; 'A Few Practical Illustrations of the Value of Photography in Law and Medicine,' by Mr. R. Biggs.

"Your Council has to report that some alteration in the rules of the Bristol Museum having taken place, the subject of the place of meeting will require consideration.

"The monthly meetings have been fairly attended, the number present being nearly the same as last year.

"Your Committee regret that two of the out-door meetings could not take place on account of many of the members being from home; but consider that the attendance at the two which were held was a material improvement on last year.

"The financial position of the Association is satisfactory.

"Your Council desires to again reiterate the desirability of every individual member doing his utmost to advance the interests of the Association, both by finding new members and otherwise, and at the same time to thank those members who, during the past session, have contributed to the instructiveness and enjoyment of the meetings by their valuable papers."

Mr. G. F. POWELL proposed, and the CHAIRMAN seconded, the adoption of the Report.

Mr. H. A. H. DANIEL then brought forward the subject referred to in the notice of the meeting, viz., an International Photographic Exhibition to be held by the Association at Bristol. He reminded those present that a year ago the question was fully discussed, and it was decided that provided certain matters could be arranged, such an exhibition was desirable, but that the final decision be deferred till the following year. At the earliest possible moment, therefore, he desired to bring the whole question before them. They would recollect the Bristol Academy had been placed at their service on very advantageous terms. He had mentioned the subject to a number of photographers in different parts, and had found the matter thoroughly welcomed, and he felt sure that very little doubt need be entertained as to the ultimate success of the undertaking.

The CHAIRMAN then inquired whether any rough computation of the necessary expenses had been made, so that guarantees for that sum might be got.

Mr. DANIEL replied that such had been done, and it might be well to reconsider the items.

Mr. E. BRIGHTMAN then stated what, as far as he remembered, the total amounted to when the matter was considered a year ago; the entire subject was generally discussed; after which

Mr. H. A. H. DANIEL said he had come prepared with a resolution that he would at once propose, viz., "That subject to the necessary guarantee being obtained, an International Photographic Exhibition on a large scale be held at the Academy, Queen's Road, in 1880, immediately following the London exhibition."

Mr. E. BRIGHTMAN said he had much pleasure in seconding the resolution as proposed by Mr. Daniel, and doubted not that with everyone's best endeavours the exhibition would be a success.

The HON. SECRETARY then explained the new rules of the Bristol Museum as to meetings, and it was decided that he arrange with the committee for the Association's meetings during the ensuing session.

A vote of thanks to the Chairman closed the meeting.

It was understood that at the November meeting the negatives taken by various members at out-door meetings would be exhibited.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE ninth ordinary meeting of the above Society was held in 5, St. Andrew's Square, on Wednesday evening, October 1st, Mr. R. G. MUIR in the chair.

Messrs. Thomas Kerr, Matthew H. Speedie, Alex. Martin, and Lee were admitted members.

Mr. DAVIS read a paper "On Failures in Carbon Printing." In introducing his subject he stated that his object in writing the short paper was more with the view of getting than giving information.

The CHAIRMAN said that the Society was indebted to Mr. Davis in a great variety of ways, and his readiness to undertake duties that properly belonged to others who failed at the appointed time showed that Mr. Davis took a pre-eminent interest in the welfare of the Society. Mr. Davis had touched on almost all the failures in carbon printing. Concerning reticulation and allied troubles, he had often entirely removed or greatly reduced them by the use of methylated spirit, and he believed, for similar reasons, that it had been found of service in gelatine dry plates.

Mr. MATHISON highly commended the use of alcohol in the production of gelatino-bromide negatives. He sometimes found it of advantage to use it in every stage of the process—the emulsifications, washings, developings, fixings and dryings.

Mr. TURNBULL remarked that by what he could gather from various sources, he believed carbon printing, except by the great commercial firms, was practically obsolete.

Mr. MOFFAT observed that with the most persevering care he still found he had to put up with ungovernable eccentricities in the carbon process.

Messrs. CRAIG-CHRISTIE and Mr. AIRD also took part in the discussion, and

Mr. DAVIES replied by answering several of the points raised, and, in answer to Mr. Pillans, he said that apart from the idiosyncrasy of the individual, if the hands were free from wounds, the bichromate was quite innocuous.

Mr. BRIGLEMAN exhibited an ingenious instantaneous shutter invented by himself, which was examined with much interest.

Mr. TURNBULL showed a dark slide constructed with paper, simple, efficient, cheap.

The SECRETARY laid on the table a large contribution of work executed by the Autotype Company; also a select contribution from the Platinotype Company. These pictures were for the Society's albums, and were remarkably fine samples of the various methods.

The SECRETARY was instructed to acknowledge the contributions, and to convey the best thanks of the Society for their valuable additions to the albums.

Votes of thanks to Messrs. Davie, Brigleman, and Turnbull, and the Chair, terminated the proceedings.

MANCHESTER PHOTOGRAPHIC SOCIETY.

The Annual Meeting of this Society took place at the Memorial Hall, on Thursday, the 9th inst., Mr. CHARLES ADIN, the President, in the chair.

After the minutes of the previous meeting had been read and confirmed, Mr. W. J. CHADWICK, the Hon. Secretary, read the following

Annual Report.

"Your Council have much pleasure in presenting the twenty-fourth Annual Report of this Society.

"A retrospective survey of the past year shows that seven new names have been enrolled upon the list of members as against ten resignations which have been tendered and accepted, and the total number of members of your Society now is sixty-seven, all told.

"We regret to have to state that, notwithstanding the very attractive character of the proceedings at the various meetings of the past session, there has been a diminution in the number of attendants as compared with last year. We notice the attendance stands in the proportion of 29½ as against 33.

"The February gathering, which was styled an 'extra' meeting, proved a success in every sense, and might be called *the* evening of the session. Amongst the subjects that have been laid before you was an address from the President and six papers. This in itself is suggestive of an advancement of the right kind, and something ahead of other years.

"The following is a *resume* of the various communications to the Society during the year:—

"'Negatives and Artistic Photography,' by Mr. C. Adin; 'Combination Printing for the Stereoscope,' by Mr. S. H. Ashley Oakes; 'W. J. Chadwick's Duplex Lamp,' by Mr. M. Noton; 'Reminiscences of a Photographic Trip to Germany,' by Mr. J. Amble; 'Patents in Connection with Artificial Light used in Photography,' by Mr. W. J. Chadwick; 'Collodio-Bromide Emulsion Process,' by Mr. W. B. Wood; 'Photographic Societies,' by Mr. W. J. Chadwick.

"In addition to the foregoing, we are indebted to various gentlemen for the exhibition of many interesting and ingenious apparatus used in and connected with photography, and also for the display of certain photographic results and specimens of our art, amongst which we might particularly name—

"The ingenious clock dial for attracting the attention of the sitter, contrived by Mr. A. Brothers, who also, in connection with several other gentlemen, experimented with the magnesium light for photographic purposes. To Mr. J. W. Leigh is due the credit for having brought several fine specimens of landscape photographs, and a silver-print washing box, as well as a very simple back-pressure valve. Mr. Knott is remembered for having exhibited a duplex glass for the flame chambers of the sciopticon, and also some silver prints exposed and printed by the electric light. Mr. H. Garside also exhibited some prints produced under similar conditions to those just mentioned. Mr. G. Gregory has brought before you many charming portraits and a few hand sketches. Mr. Watts displayed and described a novel electric battery, which he had contrived to fit inside the sciopticon, for use with that instrument for scientific projections. Mr. James Young showed a transparency on a gelatine plate, printed by the light of the moon. Mr. J. Pollitt exhibited an excellent photograph of an interior taken on a wet plate by the aid of the electric light.

Mr. W. G. Coote has upon more than one occasion brought before the members his excellent landscape photographs, both in prints and negatives. Mr. T. J. Chapman sent a novel tripod. Mr. G. A. Brookes ably conducted a lantern exhibition of slides prepared by the members, and also other slides at the extra meeting. Mr. W. J. Chadwick sought attention to the operation of the oxycalcium lime-light apparatus, invented by Canon Beechey thirty years ago for dissolving with one light only; a duplex lamp for the sciopticon, using gas instead of oil; some filigrane pictures by Mr. Woodbury; a small binocular lantern and lecturer's outfit; a small camera made expressly for lantern work; a Woodbury photometer; several gelatine negatives, transparencies, and enlargements; and an instantaneous shutter.

In addition to the foregoing members we have to thank the following commercial firms for kindly lending their various specialities:—Messrs. W. W. Rouch and Co., for a novelty in cameras; The Sciopticon Company, for a new sciopticon; Messrs. Newton and Co., for an improved magic lantern; Messrs. Marion and Co., for rolling press and other novelties; Messrs. J. Avery and Co., for backgrounds; Mr. John Moule, for a pyrotechnic lamp; Messrs. Hermagis, for portable cameras; Mr. L. Warnerke, for tissue negatives.

We are also indebted to Mr. William Brooks, of Reigate, for a collection of beautiful lantern transparencies, enlargements, and two series of subterranean photographs; while in the name of the Society, as a body, your Council tender their grateful acknowledgment to the Edinburgh Photographic Society for the presentation of a beautiful photograph in carbon, and also to the Photographic Society of Belgium for their *Bulletin*.

After advertizing to these different features of interest which have characterised our proceedings, and despite the fact that the outdoor meetings were not made so much of as they might have been, your Council consider they have good grounds to congratulate the members upon the healthy tone which generally pervades this Society. It will now fall to the lot of our worthy Treasurer to lay before you the figures which go to build up our financial status.

The reading of the report was followed by the passing of the accounts, presented by Mr. W. G. Coote, the Treasurer, and a balance sheet was given to each member present.

The nomination papers were next passed round to the members for the election of officers for the forthcoming year, and whilst the ballot papers were being scrutinized, Mr. Joseph Greatrex and Mr. James S. Watson were unanimously elected members.

Mr. M. Noton (who was too unwell to attend the meeting) had sent a very good photograph of the new Bessemer telescope now in course of construction by Messrs. Galloway and Son, engineers, Manchester.—Mr. J. W. Wade exhibited a large number of very excellent landscape photographs, from gelatine negatives, with many instantaneous views amongst them.—Mr. G. A. Brookes exhibited a capital photograph by the Vanderwyld electric lighting method.—Mr. Scofield passed round several gelatine negatives developed in various ways, and characterised by a peculiar red colour, which he considered was caused by over-exposure. A discussion on gelatine plates followed, and various hints were thrown out by some of the members.—Mr. J. W. Leigh exhibited a large number of 11 by 9 prints from collodio-albumen negatives, taken during the past year and developed by the alkaline method. These secured universal admiration, and great surprise was expressed when Mr. Leigh informed the members of the short exposures he had given—in some cases not more than five minutes, even to subjects embracing moderately dark foliage.

Mr. G. GREGORY said he had a very curious enlargement to show. It was a gelatine negative, the film of which, having become loosened from the glass, had expanded, but the image was perfectly sharp, notwithstanding.

Mr. T. CHILTON, Mr. J. SCOFIELD, and the SECRETARY said they had experienced the same effect many times.

Mr. GREATREX inquired as to the origin of spots in two gelatine negatives he had brought to the meeting, and was informed that they were caused by damp.

The result of the ballot was then announced as follows:—

President—Mr. Charles Adin.

Vice-Presidents—The Rev. Canon Beechey, Mr. Alfred Brothers, Mr. John Chadwick, Mr. J. W. Leigh, and Mr. N. Wright.

Council—Messrs. G. A. Brookes, T. J. Chapman, Arthur Coventry, George Gregory, Thomas Heywood, G. T. Linn, John Pollitt, John Scofield, W. B. Wood, and James Young.

Treasurer—Mr. W. G. Coote.

Honorary Secretary—Mr. W. J. Chadwick.

A hearty vote of thanks was passed to the late officers for their valuable services, and also to the gentlemen who had contributed to the enjoyable meeting that evening.

PHOTOGRAPHIC SOCIETY OF IRELAND.

The monthly meeting was held at the Queen's Institute, Dublin, Wednesday, the 9th of October, 1879, Mr. GEORGE MANSFIELD in the chair.

The minutes of the previous meeting having been read and confirmed, two new candidates for membership were proposed for ballot at next meeting.

Mr. JOSEPH WOODWORTH explained the making of micro-photographs, of which he exhibited a very large number of prints, with the aid of Mr. J. V. Robinson. A number of transparencies of microscopic objects were shown on the screen, and were the subject of much interest and admiration.

Subsequently Mr. ROBINSON exhibited a number of different views in the lantern with the object of encouraging amateurs to work small sizes, with the idea of making use of the lantern for their exhibition.

The triplex lantern used on the occasion was much admired for its great convenience combined with efficiency.

The changing box of Mr. GEORGE HARE having been exhibited, the meeting adjourned until Wednesday, 12th November, which is the date of the Annual General Meeting.

Talk in the Studio.

SECOND-HAND APPARATUS.—We have received from Messrs. Hunter and Sands an interesting catalogue of their stock of second-hand lenses and apparatus, generally by first-class makers. All readers contemplating adding to their stock of appliances will do well to consult this catalogue before purchasing.

LENSES—CAUTION!—We have once again to call the attention of our readers to a risk to which they are subject at present in purchasing second-hand lenses, which, by care, they may easily avoid. There are in circulation at present a number of imitation Dallmeyer's, which are dangerously like the originals in outward appearance. As we have before announced, Mr. Dallmeyer will willingly examine and certify any lens of his own manufacture, at any time after it has originally left his hands, hence no risk need be run; but it will be wise to submit second-hand lenses to his inspection before buying.

PHOTOGRAPHING FAINT SPECTRA.—A correspondent of the *Newcastle Weekly Chronicle* says:—"It may be remembered that in discussing Dr. Draper's researches as to the presence of oxygen in the sun, I had occasion to mention that, in his opinion, the extreme limit of dispersion had been obtained, so that no more delicate tests could be applied to the comparison of the oxygen bright lines and the bright bands in the solar spectrum which seem to correspond with them. Dr. Draper was probably quite right, so far as the question of the brilliancy of the oxygen lines was concerned. But Herr H. W. Vogel has devised an arrangement by which the photographs of very faint spectra can be obtained. He effects this by using the so-called gelatine dry plates. These are remarkable for their extreme sensitiveness, which Herr Vogel has estimated as fifteen times that of the ordinary wet plates. They remain good for years, and are already obtainable in the trade. Herr Vogel, using these, has succeeded in fixing the spectra of the little oxygen tubes prepared and studied by Herr Pöszow, thus rendering visible lines beyond the violet end of the spectrum—not observable by direct vision. It is manifest that any increase in the sensitiveness of the plates used for photographing spectra is practically equivalent to an increase in the brightness of the spectra, and when the limit of brightness has already been reached, it is by increasing this quality in the photographic plates that further dispersion can alone be employed. So that although—to refer to one research alone—Dr. Draper may be unable with the plates at present in use to increase the dispersion of the oxygen spectrum which he compares with the solar spectrum, he may with the gelatine dry-plates increase the dispersion ten or fifteen fold, and correspondingly increase the significance of the agreement between the oxygen bright lines and the solar bright bands. Moreover we may perhaps find in this increase of sensitiveness the means for determining the presence of other solar elements than those Dr. Draper has dealt with by the photographic method.

To Correspondents.

J. M.—Different prices are charged by different houses, varying from 1s. to 2s. 6d. Perhaps from 1s. 6d. to 2s. may be an average.

G. WEBBER, JUN.—The slides must of course be made to fit the groove in the lantern; or you may possibly make a contrivance to hold a larger plate. It will be better, however, to place a mask over the plate to reduce the portion shown. The size of the condenser really regulates the size of the transparency, for if the plate be too large, only a portion of it will be illuminated. You need not, however, cut down your 5 by 4 transparencies.

A. E. SMITH.—As you must know, we cater for many and varied tastes, and we assure you that they are not all of your complexion. We are always, however, obliged for a candid opinion.

AMATEUR.—We do not know of any process whereby a photograph can be converted into a printing block to print with type. There are two or three proposed methods, but they are as yet on their trial. One of the best methods yet known is as follows:—Take a photograph of the required subject and fix without toning. Now proceed to work upon the print with indian ink, converting the photographic shading into line and hatching. This done, take a negative of the print so treated, and then proceed to take a relief by means of bichromated gelatine by one of the methods which have been often described. If you cannot manage the method here indicated, you can get the nearest approximation by Leitch's process, which will cost much less than wood engraving. 2. We have not seen any method described of transferring a gelatine negative. To produce such negatives for transfer, it would be desirable, we think, to give the plate a preliminary coating of collodion.

E.—We do not know where you could see the back numbers of the *Journal* in question. 2. A tombstone epitaph is too grave a subject for making jokes upon.

C. H. EVANS.—There is no better plan of converting an old used up negative bath into one suitable for printing purposes than precipitating the silver, converting it into nitrate, and making a new printing bath. In our experience a doctored negative when used for printing involves many troubles, and the prints refuse to tone well.

BROMO.—You should have described the precipitate. No precipitate should be thrown down on mixing chloride of gold solution with acetate of soda. The slow toning seems to suggest the presence of some impurity.

W. W.—We prefer the results of the collodio-chloride process; but we have some doubts as to its fitness for the "smoothed" surface of the opal glass, if by that term we understand a surface ground but not polished. We have tried some samples of collodio-chloride on a ground surface, and the film split up on drying. The collodion film on a ground surface is resting on a series of points, the summits of small hills with valleys between, and if the film be of a contractile character, it is easily split in the portion over the valleys. A very powdery sample of collodion probably would not behave in this way; but it would be safer on a polished surface where the film is in perfect contact all over. We have not tried a chlorized collodion and silver bath; but we should not pay much heed to the authority you quote, as one of little practical weight. 2. In fixing the plate may remain at rest. 3. We prefer the quality of the pyro developed negative, and should not wish to tone them; but we should think it would be quite possible to do this with chloride of gold. 4. We believe there is tolerable uniformity of light and brilliancy; but we cannot state that it is absolutely constant, as occasional faults in the wire or ribbon at times cause a little irregularity. The fumes may be carried off, we believe, by good management: how far it is easy we cannot with certainty say.

A REGULAR SUBSCRIBER.—For card portraits your No. 1B and a quarter-plate camera will answer much better than the large camera and lens of long focus. The quick-acting No. 2 Ross will also answer well. 2. It depends upon which kind of dry plate you use. For collodio-bromide or gelatine the alkaline developer is best.

LAUDER BROTHERS.—We regret that we have not the address of Professor Krippendorff, and hence cannot forward the letter. His article appeared in one of the Continental journals.

TRANSFER.—The black or bronzed and opaque effect in developed collodion images is due to under-exposure and over-development. Whenever the development is slow, and requires to be pushed far, detail in the shadows is apt to be buried and invisible by reflected light. Full exposure and rapid development are very important in securing good results in producing collodion prints. Warm tones are best secured, also, by full exposure and quick development. Your formulae ought to yield good results. A good light is very important. Good collodion prints cannot be produced in a dull light.

CAPTAIN TURTON.—We will write shortly. Several correspondents in our next.

The Photographic News, October 24, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

A NEW IMPERIAL OBSERVATORY—TWENTY THOUSAND POUNDS FOR RESEARCH—A NEW FORM OF PORTRAIT—PHOTOGRAPHS OF THE KHYBER AND JELLALABAD.

A New Imperial Observatory.—The Astronomer-Royal for Scotland, Professor Piazzi Smyth, has made a very good suggestion: he proposes that some good should accrue to scientific men from our occupation of Cyprus. The clear atmosphere and sunny climate of the island renders the locality peculiarly appropriate to the establishment of an observatory, and Professor Smyth proposes that Government should be urged to undertake the work. It would be an Imperial Observatory, and its records would be available to those living in Great Britain as to other inhabitants of the empire. There is certainly a good deal of wisdom in the suggestion. We are much in want of a post of observation to supplement that at Greenwich; in fact, Mr. Smyth humorously wouders how astronomers can possibly exist in such a dull climate as England. Photographers, especially during the past year, have no need to be told how rarely the sun makes its appearance among us near the metropolis, but if there were any doubt about it, the Astronomer-Royal's records of sunshine at Greenwich, which are regularly published, would supply the information. At this time of the year, indeed, murky skies, especially towards evening, are the rule and not the exception, and of all places in the world Greenwich is about the worst, one would think, for making astronomical observations. The vast factories in the neighbourhood, with their tall chimneys belching forth the blackest of smoke, let alone the big steam colliers and shipping on the river, that pass up and down at the very foot of Greenwich Hill, all contribute to make the atmosphere thick and hazy. The sun's disc looks as round and red sometimes as if you were looking at it through smoked glass, and yet at Greenwich we profess to make the finest of observations, and our staff of astronomers there are provided with the most delicate of instruments. Surely it is high time we had our principal observatory in some more eligible situation; and we consider that if a supplementary establishment could be provided, moreover, at Cyprus, it would, indeed, furnish valuable results. We could not do at Greenwich anything approaching the work conducted by M. Janssen at Meudon. His pictures of the sun, taken in the space of $\frac{1}{1000}$ and $\frac{1}{3000}$ of a second, which have created a sensation among astronomers, could not be produced at Greenwich, with all the clever staff and perfect instruments that we possess. The hazy atmosphere would prevent the use of the astronomical camera two days out of three, and the disc pictures produced would never be so perfect by reason of the risk of accidental defects that would be produced by the thick vapour upon the photographic film. On the other hand, a photo-astronomical observatory erected in a clear bright climate like that of Cyprus, on one of the slopes of Mount Olypus, would undoubtedly be of singular value. We remember seeing, some time ago, a series of photographs obtained by Dr. Hermann Vogel on Mount Etna, when that gentleman was engaged some time since with a British scientific expedition in the Mediterranean, and the clearness of the atmosphere in this case was very striking. With such opportunities at our disposal, it really does seem strange that we should even attempt to take astronomical observations, whether optical or by means of the camera, within the halo of a great city like London.

Twenty Thousand Pounds for Research.—For a fourth time the Royal Society will take upon itself this year the task of dividing the sum of £4,000 among investigators, as an encouragement or payment for research. Government, it appears, has decided that the sum shall be paid for five consecutive years, and at the end of that time a further

consideration will be given to the subject. Thus the end of this year and end of the next are the only opportunities that yet exist for the reward of researchers, and those, therefore, who have claims, real or imaginary, and have, perhaps, a little interest besides, will do well to come forward at once. The first question that will necessarily occur to our legislators at the end of the term, when £20,000 have been expended, is, what have we got for the money? Will it be worth while to spend another £20,000 to secure the same results? No doubt those who have awarded, and those who have received, the grants, will be of one mind, and be quite ready to go on again, since it is both pleasant to have patronage to bestow, and to be recipient of a money windfall. But it will be difficult, we suspect, to show that the money for the most part has got into the hands of those for whom it was intended, from the fact that needy investigators are just those who are kept in the background and have a difficulty in making themselves heard. From a perusal of the list of recipients, they appear to be well-to-do chemists, physicists, and the like, who enjoy tolerable incomes, but to whom doubtless an addition of two or three hundred pounds has not been unwelcome. They will be found, too, with one or two exceptions, to be men of quite mediocre capabilities, who have never done anything beyond ordinary work, and are never likely to. Under these circumstances, possibly, other professional men in the country may ask that their turn should come, and that a yearly grant of £4,000 should be given for the encouragement of literature, the drama, &c. We have no doubt at all that there would be plenty in other walks of life quite ready to receive an addition to their income, and quite as capable of doing work *pro bono publico*, as any professional researchers.

A New Form of Portrait.—A new form of portrait claims attention at the Exhibition under the name of panel portrait. The style looks something like a tall cabinet, and, if we mistake not, is somewhat similar to the promenade portrait which Mr. Valentine Blanchard brought before the public some years ago. The panel portrait may be very excellent for panels; but we should hardly think that for an album, or even for an accepted form, it is desirable. A tall lady in a long dress, in which the latter is to play the principal rôle, may be well suited in a picture of these elongated dimensions; but the panel is hardly adapted for anything else. At the same time, we believe an incentive might just now be given to photographic portraiture by the introduction of a fresh style, and for this reason we could not criticise too harshly attempts in this direction. The cabinet picture is now so firmly established, that it has, much to the interest of photographers, elbowed the carte rather on one side. Cabinet albums are now to be seen on drawing room tables as frequently as the carte album, and it would be well indeed if photographers could start some equally favourite form of novel dimensions. But the matter is difficult, from the fact that fashion has a good deal to do with it, and, like other novelties, you depend a good deal upon the Royalty and the Upper Ten for popularity. Cannot our Royal photographers do something to aid in the matter?

Photographs of the Khyber and Jellalabad Pass.—It is interesting to find the Khyber Pass, Jellalabad, and other places connected with the Afghan campaign on view at the Exhibition just now. They have been added, we hear, through the kindness of Lieutenant Darwin, the honorary secretary, and constitute at this moment one of the greatest attractions. They were not exhibited on the opening day, and hence escaped a notice from the press, otherwise we feel sure that numerous visitors would have flocked to see them. But why not remedy this defect at once? An announcement in the papers, by advertisement or otherwise, should certainly be made of this strong point of the Exhibition, and would add greatly to the popularity of this year's gathering.

FRENCH CORRESPONDENCE.

PROPOSED FORMATION IN FRANCE OF A GENERAL GUILD FOR PHOTOGRAPHY—IDEA FOR ESTABLISHING A BOND OF UNION BETWEEN THE PHOTOGRAPHERS OF ALL NATIONS—DRY COLLODION PROCESS OF M. FABRE, OF TOULOUSE—FURTHER REMARKS ON THE PROCESS OF OBTAINING A PHOTOGRAPHIC IMPRESSION THROUGH PERMEABLE PAPER—VAN MONCKHOVEN'S PHOTOMETER FOR THE STUDIO.

A General Guild for Photography in France.—At the last meeting of the *Chambre Syndicale de la Photographie* the subject of extending to all photographers throughout France the benefits of a trade society was much discussed. It was felt that the plan of making use of the machinery of the Association itself would be checked by the want of the necessary adhesions, as the number of its members scarcely amounts to thirty. Up to the present, the different photographic societies have, in conjunction with this Association, represented, either individually or in combination, the general interests, as well as those of a purely trade character, of the whole photographic body. But, of course, now that the photographic industry has received so wide a development, and one which is still further increasing from day to day, it becomes necessary to establish a perfect and well-marked line of distinction between photographic societies whose special object it is to encourage and note the technical progress of our science, and the *Chambre Syndicale*, whose action is more particularly limited to the promotion, defence, and amelioration of the professional and purely commercial interests of photographers generally. There is, therefore, no reason to feel surprised that the latter Association has not drawn to itself more adherents, nor that the idea of extending its sphere of operations has not been previously entertained. To confess the truth, our art is not so ancient as to make it remarkable that it has not yet compassed a commercial organization so complete as the trades of wholesale and retail grocers, of goldsmiths, of drapers, &c., for all of which trade societies were formed centuries ago, and developed into complete corporations, each with its own officers and governing body. The few questions of detail which must be settled in order that the whole of the photographic body in France may be properly represented by a central guild elected from among its members form only a secondary consideration; it is a matter of principle rather than of any particular means more or less open to discussion. In fact, the opinions of all those interested in the subject are perfectly unanimous on the question of principle, and soon we hope to welcome the project itself on the high road towards realization.

But why should there not be an International Photographic Union?—This is a question which faces us directly we inquire what still remains to be effected to perfect an organisation at home, though an allusion to it at the present moment may, perhaps, to a certain extent, be premature. Since, however, the idea has arisen, it will not be going much out of the way to say a few further words about it. They may be like a handful of seed thrown at haphazard into the air; it is possible that a few grains will fall on fertile soil, and that we shall later on find trees growing on a spot where formerly nothing grew or flourished. In the same way, the idea having been once let fall, we may, perhaps, at some future time, see a Photographic Union in full operation, just as we have now a Postal Union embracing a large number of countries; or again, as Conventions have at different times been established for organising a common monetary system, and for the unification of weights and measures. An international organization of photography—or, to speak more correctly, of the photographic body—might well be effected to the great advantage of our common interests, and there ought to be no difficulty in setting it going. First of all, we, here in France, must put our own house in order, and when these arrange-

ments are complete, we shall be able to bring our forces of cohesion to bear on the realization of my idea with all the greater momentum, and to appeal with energy to other countries in aid of the formation of an International Congress of the whole world of photography. Then we should be able to develop to the best effect all the advantages which our beautiful art could devise from such a bond of union, and photography would be called on to play a part continually increasing in importance in its numerous applications to industry. But I fear I shall soon lay myself open to the charge of being a scheme-monger if I keep starting new projects and am continually prophesying for the future, instead of making my readers acquainted with the facts of the present, which would probably be more in their line. Will they excuse me on the plea that what I am engaged in sowing, they may, it is hoped, be called on to reap? Already many of the ideas struck out by me have been successfully put into practice by others; it is because I believe in the future of certain processes and of certain inventions that I describe them as freely as if I were painting from nature, just as if I were present at the realisation of the idea the definite proof as to whose capability has still to be brought forward. But, at any rate, for to-day we have had enough of dreams—and now to facts!

Dry Collodion Process of M. Fabre.—In the last number of the *Bulletin* of the Photographic Society of France (that of October) I have just read a note communicated to the Society by M. Fabre, the worthy secretary of the Photographic Society of Toulouse, to enable him to take part in the dry process competition. By the terms of this competition a prize was offered "for a preparation which, while possessing the greatest durability, should, when flowed over glass or any other lighter and less brittle support, yield a film equal in sensitiveness and completeness to that of wet collodion." M. Fabre appears to have confined himself as closely as possible to the conditions of the competition. The following are the different preparations which he describes:—

Collodion.—Alcohol at 40°	...	500 cub. centim.
Ammonium iodide	...	20 grammes
Cadmium bromide	...	10 "

Dissolve and add—

Pyroxyline in powder	32	"
----------------------	----	---

Afterwards, when the pyroxyline is absorbed, add by drops, with continual shaking:

Sulphuric ether at 60°	...	500 cub. cents.
------------------------	-----	-----------------

When it is well settled, decant, and add to the portion which is to be sensitized, about an hour before pouring it into the dish, 5 drops of glacial acetic acid to every 200 cub. centim. of collodion; then shake up well. The collodion is then poured out into a porcelain dish, and allowed to evaporate, when a skin will soon form on the surface; this must be broken down, and mixed with the still viscous mass of collodion by means of a glass rod. At length the collodion sets into a firm jelly, and, when it no longer sticks to the fingers, the silver bath is applied. This consists of—

Silver nitrate	120 grammes
Distilled water	1000 "

Then add a ten per cent. solution of ammonium iodide in alcohol, sufficient in quantity to produce a precipitate of silver iodide, which does not re-dissolve on shaking. Proceed now as in the ordinary emulsion process. Washing is effected by a special method, in which the distilled water is renewed several times, and then the following *preservative* is introduced in contact with the emulsion:—

Water	1000 grammes
Tannin	80 "
Phenic acid	1 gramme

to which, after filtering, are added 60 cub. centim. of alcohol of 40°, and the liquid is again filtered. After this contact the emulsion is dried by small quantities at a time in a drying oven at a temperature of 40° C., and it should be

noted that a moderate heat increases the sensibility. The final emulsion is made by putting 15 grammes of dried emulsion into a flask and covering it with 80 cub. centim. of alcohol at 40°, in which is dissolved a gramme of tannin; the latter must have been dissolved in water, carefully filtered, and then crystallised out. After standing for a couple of hours 100 cub. centim. of ether at 60° are added, and the whole is thoroughly shaken; then about 75 cubic centim. of normal collodion added. It is again shaken several times, and may be used in about three or four days.

Support.—The best support is paper coated with a thick film of collodion, and varnished with caoutchouc after Warnerke's method; gelatine steeped in alum may be substituted for the caoutchouc. The paper is first coated with thick 3 per cent. collodion containing 1 per cent. of stearine, and when this film is dry it is again coated with the alumed gelatine, according to the formula of M. Jeanrenand. On this film the emulsion is flowed. Before treated with these various preparations the paper must first be moistened, and then stretched over and glued by its edges to a glass plate of convenient size; when the emulsion is dry the paper is detached and enclosed in a cardboard portfolio.

Development.—According to M. Fabre, any developer may be used in his process, but he describes a new method of developing which should be very serviceable in travelling. The plates are placed one over the other, separated by pieces of blotting-paper which have been kept for some days in a box containing ammonium carbonate. After the emulsified paper has been in contact with the blotting-paper for five or six minutes it is breathed on, or, better still, it is suspended over a basin of water at a slight distance from the surface of the latter, when, provided the preservative contains tannin, or gallic, or pyrogallic acid, the image will very quickly appear. If it contains none, the image will seldom become visible, but the operation serves to retard the development. M. Plucker was the first to point out this action of ammonia; the use of the filtering paper is very convenient. The above is a resume of M. Fabre's dry collodion-emulsion process. I have been able to give no more than an abstract, which in a letter of this kind must necessarily be a short one. It remains to be seen whether the gelatino-bromide of silver preparations cannot effectively be substituted for those delicate and complicated washed emulsions. There is, however, in the Fabre process much to be learned to the advantage of photographic science.

Printing through a Permeable Paper.—If I once more recur to the application of the *Papyrograph* to photography it is because I believe that in it will be found a really valuable means of effecting photo-mechanical printing. In place of gelatine, it would be better to use bichromated albumen, and to apply the positive, which may be either a photograph or a drawing by hand, to the reverse side of the thin prepared paper, and in this way to expose it to the action of light; a half-tissue paper would answer the purpose very well. After a sufficiently long exposure, the prepared paper should be placed in cold water; the latter would dissolve all the parts that have not been acted on by light, and the paper in those places would remain permeable. By proceeding thus, very clean pictures could be obtained with great facility. The solution for preparing the paper might be made thus:—

Dried white of egg	25 grammes
Common water	100 "
Ammonium bichromate	3 "

The paper should be coated only on one side, and the non-coated side should be exposed to the negative. Inks and colours for printing may be prepared in an infinite number of ways.

Dr. Van Monckhoven's New Photometer.—In my last letter, published in the PHOTOGRAPHIC NEWS of the 26th September, I gave a brief description of the new photometer invented by my friend Van Monckhoven. The action of this instrument, as I then stated, depends on the decom-

position of a solution of uranic oxalate, which is converted by the action of light into the corresponding uranous salt. The volume of gas resulting from this decomposition is exactly proportional to the intensity of the light. As the estimation of any quantity of gas is a very delicate operation, Dr. Van Monckhoven has contented himself with measuring the height of a column of liquid maintained by the pressure of the gas—or, rather, produced by the gas taking the place of a quantity of liquid at the top of the flask—while the liquid thus displaced is driven into and ascends in a graduated tube. I have, without any difficulty, verified the statements of my eminent colleague. The preparation of the uranic oxalate is easily managed, and the clear directions that he has given facilitate all the other details of the manipulation. Even where the light is weak and diffused, its action upon the solution is very visible. I have only been able to arrest it by placing the instrument in absolute darkness. I have found the use of a bottle with two necks preferable to that of the ordinary flask; the second neck is stoppered with an imperforate india-rubber cork, by removing which the gas that has accumulated at the top of the bottle can be allowed to escape, and by pressing more or less on which the column of liquid in the capillary tube can be made to stand at a fixed point, being the standard from which the gradation commences. It seems quite clear that by means of this instrument, at any time of day and with any kind of weather, cloudy or fair, the intensity of the light may be determined by reading the number of units of length that the column of liquid rises in a certain unit of time. My own experience is, that the unit of length should be a millimetre, and the unit of time a minute; but in order that experiments made in different laboratories may be capable of being compared one with another, it will be necessary to use instruments that are perfectly identical both as regards the capacity of the flasks and the calibre of the tubes; or they may be graduated in the same way as is done with ordinary thermometers. There yet remains, however, to be determined how the same apparatus behaves at the end of a certain time—after, that is to say, the standard of the uranic oxalate solution has been lowered by decomposition. This point I am now engaged in investigating, and in my next letter I will state the result of my inquiry. I attach so much importance to this subject that I am taking great pains to study it in all its bearings, and I shall not fail to lay the fruit of my researches before the readers of the PHOTOGRAPHIC NEWS.

LEON VIDAL.

GERMAN CORRESPONDENCE.

BY DR. VOGEL.

THE DISSOCIATION OF THE ELEMENTS—CHLORINE A COMPOUND BODY—THE DIFFERENT CONDITIONS OF BROMIDE OF SILVER AND THEIR RELATION TO EMULSION—MONCKHOVEN'S RESEARCHES.

We are living in a time of strife and schisms. The political world was always embroiled in some kind of wrangle or dispute, but now it seems the chemical circles are even more disturbed and divided.

Lockyer goes straight for the elements, and places their very existence in doubt. He speaks of "so-called hydrogen," "so-called calcium," as if the theory of the existence of those bodies was an exploded fable of years ago. Fortunately the great body of chemists are not so sanguine and revolutionary; they stick to their old elements, and will not be convinced of their being compound bodies unless more weighty reasons are advanced to sustain this assertion; and we therefore may yet feel at liberty to speak in photography of real iron and real silver, instead of "so-called iron" and "so-called silver." Of late, however, doubts have been raised as to the elementary integrity of another interesting photographic body—chlorine. It has long been a well understood fact that one volume of chlorine weighs 35.5 times more, and one volume of oxygen

weighs 16 times more, than one volume of hydrogen. Victor Meyer has now proved that with oxygen this relation remains unchanged, even when the gases are heated to 1,000° C. and more, while with chlorine it is otherwise. At 1,242° chlorine weighs not 35.5 times as much as hydrogen heated to the same degree, but only 23.6 as much, or two-thirds of 35.5. A similar fact is observed with iodine when heated, and this singular phenomenon gave rise to the oft-repeated, and—especially by Schoenbein—vigorously defended assertion that chlorine is a compound body—the oxide of a so far unknown stuff, murium. Victor Meyer treats this matter with extreme caution; he wants to gather more material, and will make further experiments, letting the chlorine, heated to 1,500° C., act through a diaphragm. More than this he does not say in his report to the German Chemical Society, but the busy newspapers, always ready to pounce upon sensational news, even of doubtful origin, already brought the report that Meyer had succeeded in dividing chlorine, obtaining oxygen thereby. The confirmation of this report has not come yet, but in case it should prove true, then all our old theories about the combination of many important photographic bodies must of needs be relinquished. I myself have some doubts yet in regard to the matter. If chlorine is decomposed already at 1,500°, it would with more reason yet be decomposed by the electric spark, the temperature of which is estimated to exceed 20,000° C.; and if thereby oxygen is set free, oxygen lines would be visible in the spark spectrum of chlorine; but of all this nothing can be observed. These experiments and observations seem to offer, so far, interesting points only to theorists, but similar theories have often exercised the greatest influence upon the practice. The whole manufacture of our aniline colours rests on a theoretical basis, and, according to Monckhoven's recent publications, photography begins now, too, to draw benefit from certain hitherto unnoticed seemingly only scientifically interesting facts, concerning the properties of brome-silver.

For the photographer there exists only one kind—or chemically expressed, one modification—of brome-silver, but it is easy to show that brome-silver, as such, appears in many different conditions. When, for example, brome-silver is precipitated with an excess of nitrate of silver, a cheesy, dark-yellowish precipitation is obtained, while when treated with an excess of bromide of potassium or ammonium, the bromide of silver appears light yellowish and powdery, showing much less sensitiveness to light than the former precipitation after having been washed and dried. We have, consequently, two different modifications of the bromide of silver. But the celebrated Belgian chemist, Stas, who studied the combinations of silver with extreme minuteness, states that he did not find two, but six different modifications of brome-silver.

He makes distinctions between: 1, the spotted white; 2, the spotted yellow; 3, the powdery intensely yellow; 4, the powdery white, pearly; 5, the grained yellowish white; 6, the crystallized intensely yellow. Stas furthermore states that brome-silver, which was usually considered insoluble in water, is really soluble in water to a marked degree, at a temperature exceeding 33° C., when in a spotted or powdery condition. Unfortunately, Stas did not extend his researches to the relative sensitiveness to light of the different kinds of brome-silver, but recently Monckhoven has shown that that these various conditions which brome-silver appears in are a very important factor in the production of gelatine emulsion, which has of late become of so much importance. He states that in manufacturing brome-silver emulsion, at first brome-silver of a very inferior sensitiveness is obtained, which, however, through extended emulsification—*i. e.*, through being kept liquid in a warm state—is changed into a much more sensitive modification. The object of emulsification is, consequently, to work a modification of the brome-silver.

Monckhoven tried to obtain this sensitive brome-silver

modification by a different process, as the protracted emulsification and washing is very apt to produce decomposition of the gelatine. He puts hydrobromic acid (H Br) to gelatine, shakes the same well with carbonate of silver, and thus is said to obtain the sensitive modification of brome-silver without having recourse to the long emulsification. Monckhoven takes so much hydrobromic acid as is necessary to precipitate 10 grammes of nitrate of silver, dissolves this H Br in 200 grammes water with 2.5 grammes gelatine. He precipitates furthermore 10 grammes nitrate of silver with carbonate of soda, and washes out the precipitated carbonate of silver with pure water. Upon this carbonate of silver he pours the acid solution of gelatine, shakes well, and lets the whole stand about twelve hours at 50° C. Gradually brome-silver is then formed, which is distributed equally all over the gelatine, and after adding 10 grammes of gelatine, the emulsion is ready, and it is not necessary to wash the same, as it only contains free hydrobromic acid, or free carbonate of silver, which, according to Monckhoven, does not matter. Monckhoven extols the sensitiveness of his emulsion, but, unfortunately, he fails to give all the necessary details, so that his process, in other hands, has produced less favourable results.

(To be continued)

HOW TO AVOID BLUE SPOTS ON ALBUMENIZED PAPER.

BY FRITZ HAUGE.*

It is well known that with paper recently albumenized the coat of albumen very often separates from the paper in the soda bath, or rather in the first wash-water, with the formation of bladders or hubbles. When prints of this kind are washed for a lengthened period, or if after short washing they are allowed to dry spontaneously, unsightly blue spots will appear at the places where the bladders had formed. These blue spots can, it is true, be averted by washing the prints as quickly as possible, then laying them between sheets of blotting-paper, and smoothing away the hubbles by a firm pressure with the hand. But, unfortunately, quick washing is accompanied by the danger of allowing considerable traces of fixing soda to remain in the prints, a danger which, in this case, is all the greater owing to the fact that the hubbles offer very convenient hiding places for the soda solution to retreat into.

I have, however, discovered that these blue spots can also be avoided by bringing the prints at once from the soda bath into one of water mixed with a little *eau de Javelle* (two dessert spoonfuls of the latter in a moderate sized washing bath is sufficient). From this they are removed into a second bath of the same kind, and are afterwards treated in the usual way.

The *eau de Javelle* is essentially a solution of potassium hypochlorite in water, and this solution has the property of decomposing one of sodium hyposulphite, or, as it is now written, sodium thiosulphate. Potassium sulphate, sodium chloride, and hydrochloric acid are found according to the following equation:— $\text{HO} + 2(\text{KO}, \text{ClO}) + \text{Na}, \text{O}, \text{S}_2\text{O}_3 = 2(\text{KO}, \text{SO}_3) + \text{NaCl} + \text{HCl}$. By the change thus effected the sodium hyposulphite is entirely broken up.

On this account the treatment of photographic prints with *eau de Javelle* for the purpose of quickly removing the hyposulphite of soda is generally to be recommended. Julius Kruger was the first to point out this property; afterwards G. Gunther and Dr. Stolze, and more recently G. Rotter and E. Duhy, drew attention to it. Unfortunately, this judicious adjunct to the operation of washing photographic prints has not been extensively applied in practice, partly, no doubt, owing to carelessness, partly to ignorance.

To prepare *eau de Javelle*, take one part of calcium chloride and lixivate with 12 parts of water; filter the ley, and mix

* Photographisches Wochenblatt.

into it gradually a solution of 1 part potassium carbonate in 4 parts water, so long as a precipitate is formed. It will be found that 120 parts of the calcium chloride ley requires about 20 parts of potassium carbonate solution. Instead of *eau de Javelle* may be used *cau de Labarraque*; this may be prepared as follows:—1 part calcium chloride is stirred up with 12 parts water, and the ley decanted off. Another 2 parts of water is poured over the residu, and again decanted off and filtered. The whole is then mixed with a solution of 2 parts crystallized soda in 4 parts water, and filtered.

PHOTOGRAPHY AND THE SUN'S SURROUNDINGS.*

Now, in one sense, the relations here presented are not new. The zodiacal light has been known from the time of Childey, if not from that of Tycho Brahe. Mathematicians have long seen that it must belong to a solar appendage, rejecting utterly the doctrine advanced by some that it comes from matter travelling round our own earth. Again, the long coronal rays had been very confidently regarded by most mathematical astronomers, and, indeed, by all who had sufficiently studied the evidence, as belonging to matter near the sun. And though the zodiacal had never before been recognized during totality, and so the gap between the outermost coronal rays and the innermost part of the zodiacal seen during twilight had never been observationally filled up, yet the mind's eye of science had clearly discerned even that portion of the zodiacal. Still the recognition of the whole range of solar surroundings, in such sort that no question can any longer, it should seem, be raised as to their reality, even by those least able to follow scientific reasoning, cannot but be regarded as an important step. Many will now study eclipse phenomena with a new interest and a new purpose, who formerly supposed the theories of astronomers respecting the unseen parts of the zodiacal to be mere hypotheses, even if they were not wholly fanciful speculations. Many, in like manner, will study the zodiacal light as seen in morning and evening twilight with much greater care than heretofore. Its changes of extent, position, and lustre will now be seen to be full of interest. Whether they synchronize or not with the changes undergone by the corona, or with the varying extent and activity of the prominence region, or with the number and size of the solar spots, are questions of importance, to some of which we may hope to obtain an answer, seeing that in tropical regions, especially at elevated stations, the zodiacal (as Humboldt long since pointed out) is a conspicuous phenomenon. Whether during future eclipses the zodiacal will be traced further from the sun than by Langley and Newcomb in July, 1878, is not in reality a matter of much moment. The great point is that the zodiacal should once have been unmistakably recognized during total eclipse. That was all that was wanted to make the chain of evidence complete, even for those who cannot recognize the force of reasoning when it deduces from observation something more than was actually seen. Now that this is done eclipse observations of the zodiacal will not be wanted. They never could throw any light on the nature of the zodiacal light, except near the sun, where the long rays are. For at a distance of 6 deg. or 7 deg. from the eclipsed sun the light of our own atmosphere begins to show, obliterating the delicate light of sun-surrounding matter. As to the rays, now that their solar, or rather cosmical, nature is recognized, we may expect that they will be carefully studied. What their real nature may be is not easy to determine. That they indicate the existence of meteoric or cometic systems near the sun, as Professor Abbe believes, may be accepted as probable. Indeed, the only reasonable theory of the zodiacal is one which, as was shown nine years ago by Mr. Proctor, would lead us to expect to see

signs of meteoric streams where these rays appear. He wrote ("Treatise on the Sun," 1st edition, p. 363):—

"The sun has as an appendage a cloud of cosmical bodies, which will continue for ever, or for an indefinitely long period, as a cloud appendage. It will not be fixed, the relations of its several parts will not be fixed; on the contrary, the cloud will shift and fluctuate, its members aggregating here and segregating there; but as a clustering appendage it will be permanent. . . . The existence of multitudinous of eccentric systems implies necessarily the aggregation of meteors in the sun's neighbourhood. . . . These meteors would be severally illuminated with inconceivable splendour on account of their nearness to the sun. . . . Add to this that those approaching most nearly to him would be rendered incandescent if not vaporized by the intensity of his heat, and that most probably electric discharges would take place between them on account of the intense energy of the solar action."

But Professor Abbe's theory, that the rays he saw were themselves meteor systems, involves difficulties which he does not seem to have noticed. A meteor system would only by the merest chance appear as a beam lying directly athwart the sun. For that purpose it must lie beyond the sun. (Professor Abbe says it may lie either on the hither or further side of the sun, but a stream of meteors on the hither side would rapidly fade out near the sun, just as Mercury and Venus rapidly lose their lustre when approaching the sun in the part of their orbit nearest to the earth, or technically when approaching inferior conjunction.) Again, such a system, to appear straight athwart the sun, must lie in a plane passing through the earth's place at the time. Now, among some two hundred meteor systems through which our earth passes we find every variety of position. So that it might happen that a single meteor seen during totality would have just such a position as would make it appear to lie athwart the sun. Even that would be a strange chance. That two systems (two only being seen, be it remembered) should be thus situated would be a very strange chance indeed. But that in every eclipse ever observed the meteor systems should be so situated as to form rays apparently extending from the sun is altogether incredible. Sometimes, most assuredly, if Abbe's theory were correct, we should see meteor systems passing near to the sun without touching his disc. But beams of silvery light so situated have never been seen. There are other objections, but this may suffice here. We seem compelled to believe that the extension of the rays directly from the sun is not an accidental feature, but is due to the real extension of lines of illuminated matter radially from his globe. The explanation of the peculiarity remains to be discovered. We venture to predict that it will be related, and not remotely, to the explanation of the extension of comets' tails directly from the sun; for it is more than probable that enormous quantities of cometic matter exist in the sun's immediate neighbourhood. We would quote in conclusion another passage from the work to which we referred a few lines above, because, though written nine years ago, it corresponds well with the present position of the subject we have been dealing with:—

"To doubt what general view we should form of the corona and zodiacal light seems to savour, not of that wise caution which prevents the true philosopher from over-looking difficulties, but rather of an inaptitude to estimate the value of evidence. As to details, we may be doubtful. Other matter than meteoric or cometic matter may well be in question; other modes of producing light, save heat, electricity, or direct illumination, may be in operation in this case; and lastly, there may be other forces at work than the attractive influence of solar gravity, or the form of repulsive force indicated by the phenomena of comets. As regards also the true shape and position of the coronal and zodiacal appendage, and yet more as regards its variations in shape, we may still have much to learn. But of the general fact that the corona and zodiacal light form a solar appendage of amazing extent and importance, that they are not merely terrestrial phenomena, but worthy of all the attention astronomers and physicists can direct to them, no reasonable doubts can any longer be entertained."

THE PHOTOGRAPHIC EXHIBITION.

THE announcement of the awards of "honourable mention" in our last has, we regret to say, been the subject of adverse comment. We expressed a conviction that, in some of the cases we mentioned, medals might, with great propriety, have been awarded in place of merely honourable mention. But we are now met with a question as to the propriety of the award of "honourable mention" at all. Attention is called to the fact that no announcement was made, in the published programme of exhibition arrangements, and of the prizes offered, of any intention to award honourable mention as well as medals. Hence it is alleged that the change of programme placed some exhibitors at a disadvantage. We are asked by what authority "honourable mentions" were distributed without prior announcement? This is a question we cannot answer. Whether the original intention of the Council was that such awards should be made, and the announcement was accidentally omitted from the published regulations, or whether it was a spontaneous decision of the jury, we cannot tell. We can easily conceive that where meritorious pictures obtained the approbation of some of the jury, but not the unanimous consent to a medal, honourable mention was agreed to as a compromise; or it may be that unanimity as to a degree of merit might exist, but insufficient merit to take a medal might issue in a lower award, and since but one class of medals existed, the jury might feel that they were not exceeding their powers in making the secondary award. These, however, are but guesses on our part.

Let us, however, briefly examine this question of secondary awards for a moment, as an abstract question, without reference to the present case. It is not necessary to go into the vexed question of making awards to art productions; but assuming that the award of prizes is a beneficial stimulus to emulation, we still feel that there is danger in the classification of prizes so as to express degrees of merit, so hard to decide in works of art. In some of the great industrial exhibitions two or three grades of medals have been awarded, and a degree of merit unworthy of a medal distinguished by "honourable mention," which, as indicating a very fourth-rate excellence, fell into discredit as almost a stigma, instead of a proud distinction. We have, in fact, heard it described as a grave way of saying in effect: "This is very poor work; but it is well meant." But the effect was to

"Damn with faint praise, assent with civil leer,
And, without sneering, teach the rest to sneer."

That there are, or may be, occasions in which any encouraging notice may be a valuable incentive to fresh effort there can be no doubt. Recognition of good intention is only too rare, and should be gladly accepted when met with. The poet—Dryden, we believe—tells us of an occasion when

"They, too, had crowns who but endeavoured well;"

and one of the most graceful of modern lyrists, Mr. William Sawyer, pleads for consideration for those who—

"Battle's hottest brunt sustaining,
Only short of victory gaining,"

fail to win the "pæans and triumphal greeting" of the multitude. But there are many exhibitors at the Photographic Society's annual display to whom the patronizing pat on the back of honourable mention is an affront. Had they competed with the full knowledge that they might incur such an indignity, they would have no cause to grumble; but when the mine is sprung upon them without warning, we can understand a sense of annoyance, even if it were intended as a compliment. One thing is, however, tolerably certain, that the jury was an honest and a capable one, and, as we have before said, their awards will in the main give satisfaction.

The engineer photographers at Chatham—or, to be precise, the School of Military Engineering, Chatham—exhibit a number of landscapes of large size, all of an even high level of excellence. Some views in Wales, and some of Tintern Abbey, are very fine, and free from the opaque want of detail too common in photographs of ivy-clad ruins. Captain G. H. Verney has several good views of the same class of scenery, in some of which he has fallen into the error to which we have just referred—blackness in the shadows of masses of ivy and shadowed portions of architecture. In some cases, too (as in 74, 75, and 76), he has marred the value of his views by getting too near to his subject, and so including an insufficient portion of it to make a satisfactory picture. Alfred Pettit sends various views of English lake scenery. Many of them are very interesting, but he scarcely does justice to such a richly picturesque district, and errs frequently in the direction of blackness. Mr. J. Milman Brown sends some capital views from the Isle of Wight, and repeatedly shows skill in selection by making a charming picture of a simple lane scene. The lane scene, including Bonchurch Pond (61), is a good example, although the pond itself being in shadow gives a large mass of gloom in the picture. Whether at some other hour in the day more light could have been got on the pond we cannot say. The coast at Luccombe (82) is wild, and, probably, interesting to a geologist, but scarcely pictorial. Mr. F. Beasley's frames contain, as usual, some excellent work—neat, precise, and careful, without lacking pictorial elements. They are good examples of the Fothergill process, to which Mr. Beasley steadfastly adheres. The Rev. B. T. Thompson sends a few interesting examples of the blending of the photographer's interests with those of the angler. It has always seemed to us that the two hobbies might be well joined, the rod packing admirably with the tripod legs. Mr. Thompson gives us the landing of a trout, at least a two-pounder, we imagine, from the interest of the two disciples of the gentle Izaak. The Angler's Rest (119) is another good picture by the same photographer. Mr. A. Donald gives a similar subject, a quiet, shady pool, entitled, the Trout's Retreat (148).

The Highland scenes by the same gentleman are well chosen and characteristic. Mr. M. Whiting sends several frames of small landscapes and rural subjects, fairly representing the style familiar in exhibitions of a few years ago—clean, sharp, black-and-white pictures without atmosphere or sky. Mr. H. W. Reeves sends a frame (189) containing landscape and interiors, both good, the latter especially fine. Mr. Brightman's frame of stereos, entitled "Stray Peeps in Pleasant Places," are interesting. Mr. Arthur S. Howman's views of the Thames at Isfey are fine, bold, and picturesque. Captain Abney contributes very little this year; but his charming half dozen frames (219 and following) are very excellent. Lieut. Darwin, the Honorary Secretary of the Society, sends three very picturesque views of Tintern. Dr. Huggius sends three frames of small pictures, which are amongst the gems of the Exhibition; they are exquisite in their delicacy and pictorial value. We

recommend every visitor to take especial care to see them: they are 245, 246, and 247, the negatives on gelatine plates, and the prints by Willis's platinum process, which appears to suit them well. A frame by Mr. H. A. H. Daniel contains some very admirable pictures, well-selected, and well-treated landscapes.

We have said before that the Exhibition was distinguished by a high level of general excellence. It hence includes many fine landscapes not calling for individual notice. Amongst these are some good views in Reigate, by Allan W. Richardson; the excellent Welsh views of Mr. Seymour Conway; landscapes by Corporal James Miller, Ernest Soutter, A. Galloway, A. Clout, C. Bossetti, C. G. Cutchey, W. S. Hobson, E. Hyde, C. R. Lenthall, the Hon. Mrs. Holden Hambrough, and others, many of which possess many merits.

COPYRIGHT IN PORTRAITURE.

THE allegations in the recent libel case to the effect that the friends of Mrs. Cornwallis West had used their utmost endeavours to prevent the publication and sale of her portraits, but without success, has excited considerable interest in the question, to whom does the copyright in a photographic portrait belong? The *Solicitors' Journal* has the following remarks on the subject:—"The statement of the prosecutor in a case which has recently occupied a police court, that 'he and his solicitor had taken every step to prevent photographs of his wife from being sold,' recalls attention to the state of the law as regards copyright in photographic portraits. Photographs were placed by the Copyright Act of 1862 on the same footing as paintings and drawings; and with regard to photographs 'executed for or on behalf of any person for a good or valuable consideration' the provision is satisfactory. The person executing the negative does not retain the copyright thereof, unless it be expressly reserved to him by an agreement in writing, signed by the person for or on whose behalf it was executed; in the absence of such agreement the copyright belongs to that person, and he may recover by summary proceedings before justices, against any person infringing his copyright, a sum not exceeding £10 for each offence, negatives made for the purpose of obtaining the copies being also forfeited to the owner of the copyright. But where the photograph is not executed for any person 'for a good and valuable consideration,' but gratuitously or by stealth, these salutary provisions do not apply; for, as it has been said, no one has a copyright in his own face. The Copyright Commissioners, in their recent report, say that, 'considering the facility of multiplying copies, and the tendency among photographers to exhibit the portraits of distinguished persons in shop windows, it may be thought that there is even greater reason for giving the persons whose portraits are taken control over the multiplication of copies than there is in the case of a painting.'"

The quotation from the statute given by our legal contemporary seems to make the case simple and clear. Unfortunately, however, it does not state the whole case, nor quote the entire section of the Act. After stating that the copyright shall belong to the vendor or person commissioning or ordering the portrait, and paying for it, and on whose behalf it was executed, it proceeds thus: "Nor shall the vendee or assignee thereof be entitled to any such copyright unless at or before the time of such sale or disposition, on agreement in writing, signed by the person so selling or disposing of the same, or by his agent duly authorized, shall have been made to that effect." In short, in the ordinary procedure of a photographic portraitist's business in which a portrait is ordered and paid for, no copyright can accrue, it appears, to either party, portraitist or sitter, without an agreement in writing defining the proprietorship of the copyright.

It seems probable that the section in question was the subject of considerable modification in the passage of

the Bill through Committee, and, instead of recasting the section entirely, so as to make it clear and consistent, the modifications have been grafted on to the original draft, rendering it clumsy, involved, and uncertain in meaning. In the new Bill recently printed, the subject is dealt with in a much more perspicuous manner.

Referring to this subject, the *Times* has the following remarks:—"The sale of photographs, the law as to which has attracted considerable attention in consequence of Mr. Cornwallis West's statement as to his inability to prohibit the sale of his wife's portraits, is thus dealt with by the Government in their Copyright Bill, which was introduced by Lord John Manners at the close of the last Session. According to this Bill, the copyright is to belong to the proprietor of the negative from which a photograph is printed. But where the photograph has been made on anyone's order for valuable consideration, the proprietor of the copyright will not be entitled to sell a copy without that person's consent, or to expose it for sale or exhibit it. And the person who orders the photograph is to have the same right of preventing the sale, the exposing for sale, or the exhibition of any copy, as if he were the owner of the copyright. Similarly he is to be empowered to take proceedings in case the copyright be infringed. With regard to the duration of the copyright, which is at present for the lifetime of the artist and seven years afterwards, the proposal is to fix it at thirty years from the date of publication."

"LOOKING BACK."

BY AN OPERATOR.

CHAPTER VIII.

CRIPPLE AND RELIGIOUS PHOTOGRAPHERS—RETOUCHING!

I COULD go on for an indefinite time telling of eccentric characters in our profession whom I have met; many of whom, thank Heaven, like the glass pictures and Daguerrecotypes, have died out. I could tell you of the photographer whose parents had seriously thought of making him a tailor instead, owing to his physical infirmities—it being in the end a toss up. It is marvellous the number of cripples you would meet with in our profession a few years since! If a lad had a weak head, a wobbly back, wanted an arm or a leg, or was otherwise incapacitated to take his place alongside the ordinary tradesman, the fond parents immediately decided that photography being a light (?) and genteel business, and a little more respectable than a tailor, he should take a few lessons, and then father's savings would easily start him! This is a fact: I have known of several instances, but they are now no more. They could make a fair clean picture as the times went, and friends flocked round them, bringing others with them—indeed, I think all their customers were more or less tinged, or, I should say, influenced—by charity or pity. No matter—they lived their little lives, drooped, and died, whether by their natural infirmities or the smell of the chemicals I know not; but they left photography as they found it, neither improving it nor even keeping pace with it. I think and speak of these lame dabblers with all the pity and gentleness that the strong must ever feel for the weak. Yet I cannot help adverting to them, inasmuch that I can recollect once upon a time of wishing—actually wishing—that I had some flaming deformity about me. I had gone to fill a situation in a city where there were only three photographers then, and they were all cripples. The inhabitants seemed to think that to want an eye or a leg, or have a humped back, was a peculiarity of the business; and when I appeared among them they lifted up their hands and eyes in amazement. They would watch me—silently look over my fair proportions, and then exclaim—"Him a photographer—him! Well I never!" They made me ashamed of my strength.

I could tell you about the photographer who smudged along during the summer months in a back yard with a glass top, and delighted a winter audience as a clown over

Christmas. I could tell you about the female photographer—in most cases a vile imposition—to whom the timid and nervous ladies rushed, and to whom unruly urelins were presented by the hundred, and where the blushing youth would sometimes sympathetically wander. I could tell you about the flashing, dashing photographer who seemed to be doing so well, who was always dressed in the tip top of fashion, “with rings and farthingales and things,” who was “hail fellow, well met” with all the actors and drove the actresses out on Sundays, and yet who had to bolt one day without bidding anyone good-bye. And I could tell you about the religious photographer who never seemed to do anything, and yet who was every year building a house or buying one.

I must tell you something about this last one, for he is common, and, what is better, he is successful. Whether he is in earnest with his religion or not I don't care the value of a brass farthing. Enough that I know his style! He is suave—he is soft—he is wheedling—in fact, he verges on the lick-spittle; his maxim is a good one: more is got by licking than by kicking! He has a puritanical air, and his ready smile shows his well-kept teeth; he has a passion for shaking hands, and fondles the ladies' soft palms affectionately; he has *apropos* texts on the tip of his tongue to any amount; he wraps a tract round his eartes when he posts them; he talks in fatherly language to young ladies, and advises the young men sternly; he carries a Moody and Sankey hymn book in his coat tail, and goes to all the tea fights; he grins and smiles, quotes Scripture, and wriggles himself into every one's good graces—distributes his circulars—never enters a public house—and succeeds!

Now, you know, this is no fancy picture—he is a real bona fide photographer, and I am not joking when I tell you that I am half inclined to envy him his talents; for nothing succeeds like success. I, a man of the world, recognize and admire the attributes of my religious brother. He hath goods and chattles around him, while I am like the Bedouin of the Desert! Oh, my friends, rolling stones, like poor Geo, gather no moss! (Note: My wife has seen the last line, and insinuated that what I have lost in moss I have gained in *polish*—a very flattering notion.) To young beginners who wish to succeed, I cannot do better than advise them to follow in my religious friend's footsteps. The path is safe, and the goal is sure! One thing I will yet mention in regard to my religious friend that may be of service to his followers, and enlighten such old stagers as myself: he sends his bills out three times; twice the bill goes home endorsed “with respectful thanks;” the third time it goes he adds, “P.S.—The labourer is worthy of his hire.” This generally has the desired effect, for a P.O.O. or a cheque per return gladdens his heart.

I could tell you about the process and secret selling days, when hoary-headed rascals wandered the country, making a nice little living out of the struggling and credulous photographer. I could tell you all about the carbon process—the Saronotype—photo-crayons—Edwardtypes, and a legion of other types that would not profit any one. I slip over all those. Put the carbon process on one side, and look back over these past twenty years, and you will find the silver process—the albumen print—in almost the same state now as then. During all these years there is but one notch in the stick of time worthy of record.

Retouching!

Some of our sitters have indeed reason to thank the inventor of this art. How do you fancy Miss Freckle would have looked if she had got a print from the pure materials; or do you think Crowfoot, Esq., would have given you so nice an order if it had not been for the retouching? Indeed, now I think of it, we ourselves have reason to thank the inventor of retouching; for I am half inclined to believe that had it not been for the introduction of this gentle art, our occupation, like Othello's, would have been gone—at least, I feel sure that a great number of our present sitters would never have troubled

us if we could not spirit away the unpoetical wart or the tell-tale pimple.

Madam Rachel was a farce compared with the skilful retoucher: a few light touches of the latter's pencil, and ten years drop as if by magic off the age of his subject. The lines of care and trouble vanish; the hollow cheek is rounded; the sunken eye sparkles; the horse-shoe mouth loses its melancholy corners. It is wonderful—it is immense—the power of the retoucher.

To become a thorough retoucher one must lay in a great store of patience and perseverance.

“Every wise observer knows—
Every watchful gazer sees—
Nothing grand or beautiful grows,
Save by gradual slow degrees.”

I was slow, awfully slow, at picking it up. At one time it was my bug-bear: I could see it stand between me and good situations. The number of negatives I spoiled was enormous in my efforts to conquer it. My first false steps were in grinding the picture almost off the plate in my earnest efforts to obtain a proper tooth to my pencil, and then in using a soft B pencil that made marks of such a decided stamp that it was no wonder I got disgusted when I looked upon the miserable result: the pictures were worse than if I had left them alone. However, I was not to be beaten. I got a specimen—a German print—and went at it again. I was more cautious in roughing the varnish. I used a harder pencil, and gradually, as I toiled and worked, I discovered the secret of all secrets, viz., that the lighter the touch the more successful was the result. Most beginners, I believe, fall into the same mistake, and lean too heavily with the pencil. Another stumbling-block of mine was looking too close at the negative. Of course, this may be a matter that will entirely depend upon the eyes of the operator; but in my case I was so eager to fill up every minute flaw in the skin, that I lost the general roundness that makes the retouched picture so charming. Let young beginners mind what I say about this, and let me advise them strongly not to neglect this now all-important branch of our business. Independent of the pecuniary emoluments that the high-class retoucher every where gets, he, in my estimation, doubles the pleasure of his work. Is it not a delight to see the disappearance of skin blemishes—the rugose image slowly revolve itself into a picture round, soft, and beautiful? I know there are a certain class who cry out against retouching; they declare it takes from the character of the face, loses the likeness, and otherwise hurts the artistic attributes of the picture. This is all stuff! When I was struggling to learn the art, I would very often overload the face, but that was my inexperience. I now know at a glance where to put the touches and when to stop the process. I am in a house where we retouch every negative very highly, and I can safely say we never lose a likeness: we certainly take a few years off the sitters' ages; but this is an amiable weakness that brings us nice returns in the shape of large orders.

It is a curious thing in human nature that man, woman, or child never wish to look older or even so old as they are, and consequently the operator who can strip a few years off the sallow face of the old maid—reduce the fair, fat, and forty proportions of the widow to something trim and comfortable—give to the aged-bachelor an air of juvenality—is bound to succeed.

I cannot help thinking that old hands like myself, who had to make the best of their negatives by means of the developing and re-developing solutions, when a little blue or yellow was all the additional help that could be given to the picture, far outstrip the young ones. The young operator is rash and sanguine! If he gets a negative that is defectively lighted—a negative under or over-exposed—a negative with streaks and comets all over it—he will exclaim, “Oh, hang it! That will do, it can easily be made straight in the retouching.”

This is an awful mistake. Instead of using retouching here, you are abusing it; instead of taking it as a help to the good negatives, you are making it do the work of the chemicals or your own bad manipulation. A dirty negative, with all the retouching in the world, will never make a clean print. When my young friends get such a negative, I advise them strongly to set it aside and rectify the evil at once by taking another plate: ten minutes will do it, and the satisfaction afterwards will amply repay you.

Now I hope these few hints will be taken in the hearty manner they are given. One more word. I was for years troubled by the varnish—some was too sticky, some too hard—and I may mention now that I have discovered a varnish and an accompanying medium that work like magic. It is sold by one of our largest wholesale houses—has the qualities of being both cheap and priceless. It would be out of place to mention the name here; but, should any of my readers wish to know, they can drop a note to the Editor, when I shall be happy to give the desired information.

(To be continued).

PLATT'S TRACING APPARATUS.

BY S. L. PLATT.*

A GREAT many photographers cannot afford a solar camera, and an apparatus that would enable them to have some of its advantages will doubtless be of service to them.

The first step is to procure the enlarged sketches of the picture you propose to make. This I do by means of the apparatus which I shall describe below.

As I have said, my invention is for tracing or sketching for crayon or other portraits. It can be used by any one, and for enlarging any object that can be attached to the top, which is to contain the picture, face down. It can be made of any size, from eight by ten to life-size. The lens, the movable front for focussing, clamps for holding the movable top, which is adjusted from inside, and governs the size of the object, and the reflector to throw strong sunlight on the object, will all be seen in the diagram;

also, the table or stand upon which the paper, or material upon which to draw the image as it is reflected down, is placed. This is a very useful instrument for any gallery, as any card can be enlarged to a perfect eight by ten, or larger, to show the customer how he would appear in a large portrait, which might induce him to have one made. The one I have is intended for a ten-inch head, or from that down to eight by ten. It is two feet square at the base, four feet high, fifteen inches wide at the centre, with a twelve-inch arm to the reflector. The reflector has three movements, or six, counting the backward movements.

The movable box has only two movements, up and down,

* Philadelphia Photographer.

for governing the size of the reflection. The box is nine inches square, one inside of the other, fastened with a thumb-screw inside of the front curtain. The movable top is raised and lowered from the inside, and fastened by a clamp with a thumb-screw in front. The thumb-screw is ten inches long, to reach clear across the front. The strip across the centre, holding the reflector, is eighteen inches long. The box or frame-work is covered with soft flannel, and lined with thick yellow paper, so no light gets in save the reflected light. It will be observed that the image is very strong, and has the appearance of a finished picture. The rays falling in at the top make it a very pleasant light to work in, just right for comfort, something like twilight. It takes one to trace by measure, as all portraits do on canvas or cardboard, from two to four hours.

An artist rarely cravens two heads alike from the same picture, and do his best. I can with this make eight sketches with ten-inch head in less than an hour, and have them alike every time, for I will not change the focus, and pin the paper each time at the same place. Changing the position of the reflector does not change the reflection, as it leaves the picture every time alike. This is not usually the case with a solar printer.

I am a great friend to the solar camera, but I can, by using a condenser, do the same work by this.

THE PRESS AND THE EXHIBITION.

(From the SOUTH LONDON PRESS.)

THE Photographic Exhibition year by year grows more interesting as by degrees improvements in manipulation are perfected and progress in art attained. We are afraid that in former years a great number of monstrosities, judged from an artistic point of view, found a place on the walls; but these have gradually grown less and less, and the taste and feeling now manifested would do credit to art exhibitions of much greater pretensions. This is particularly conspicuous in the collection now on view at the Gallery, 5A, Pall Mall East; and the general public, who, as a rule, know very little of what the photographic art is capable, would do well to visit the Exhibition, for we can safely say they will be surprised and pleased. In technical qualities, the photographs of the best men of the present day are perfect, and the point at issue appears to be what is the best process which combines the greatest rapidity and excellence. Without going into details, we may say that hitherto the collodion wet process has answered most of the requirements of the photographer, and until a few months ago no other process could compete with it. Latterly, however, a gelatine dry process has been much improved—so much so, that while much more conveniently worked, it is considerably more rapid and the results are nearly equal. We say nearly, because, although isolated examples may be produced which are quite as good as those by collodion, the general quality of the work is not quite up to the high standard which the practised photographer can always ensure with the old process. This, however, may be but a question of time and experience. Of the superior rapidity of the gelatine process there is but one opinion; and when we state that a swallow in the act of flying, as well as its reflection in a pool, can be photographed as sharply as though the bird had paused with its wings outstretched for the purpose, some idea can be formed of its marvellous actinic quality. Of the gelatine process there are any number of examples in the present Exhibition, and foremost are those produced by the South London exhibitors. Nothing finer in this way than the landscapes of Mr. Joseph Gale, of 22, Long Lane, Bermondsey, has ever been shown. As soft and as delicate as the best productions of collodion, they have also that desirable atmospheric effect which we look for in vain in so many photographs. Mr. Gale is the fortunate gentleman who has captured the swallow referred to above, and the picture (No. 6) is altogether a charming one. Not less so are "Brixham Trawlers" (Nos. 4 and 5), "On the Mole" (Nos. 51 and 53), and many others. Small in size, they are perfect in composition and technique. Mr. S. Payno Jennings, of 6, Rosendale Road, West Dulwich, is another photographer who has earned a reputation for artistic work, and his contributions,

though to our thinking not so interesting as his "Examples of the Poets" last year, show fine taste and excellent judgment. He sends eight pictures illustrative of English and Irish scenery. Of these, three are by the dry gelatine process, and, fine as they are, they are inferior to those by collodion. There is a fulness and richness of effect in the latter that we miss in the former, which, by contrast, appear somewhat flat. Mr. Jennings' work is, however, undoubtedly exceedingly good, and as an adept in the use of the collodion process, he deservedly occupies a high position. Mr. Mathew Whiting, of Lavender Hill, a veteran exhibitor, displays all his wonted skill of manipulation in a series of very interesting views. Captain Verney, of Esher, Surrey, has some excellent landscapes, and Dr. Huggins, of Upper Tulse Hill, three views, noteworthy from the fact that they were developed four weeks after exposure. Dr. Huggins' pictures are printed by Willis's platinum process, of which we shall have something to say farther on. Mr. B. King, of Croydon, also exhibits an instantaneous picture (No. 26) taken on a gelatine plate; Mr. Allan Richardson, of Croydon, a view near Reigate; and Mr. Wainwright, Jun., of Hoe Place, Woking, some clever instantaneous studies on gelatine plates made by himself. Mr. W. Bedford shows landscapes possessing all the care and clearness which distinguish his work. If Mr. Bedford could get rid of a certain mechanical look which his pictures have, they would gain immensely. M. S. G. Payne, of Aylesbury, gives evidence of his industry in a large number of very interesting landscapes and studies; and Mrs. Payne shows some clever pictures of flowers and still life. Mr. Vernon Heath's views of Burnham Beeches are perfect in their way, and Colonel Stuart Wortley's sea and cloud effects could not well be surpassed.

The Exhibition is not particularly strong in portraiture, but what there is good. Mr. Rocher, of Chicago, fairly takes the palm for variety and artistic excellence in what may be termed ordinary portrait work—a collection of "Panel" portraits being particularly noticeable. Messrs. Russell, of Worthing; M. Boucher, Brighton; and Mr. Byrne, Richmond, all exhibit good work. There are few attempts at what once used to be regarded as the be-all-and-end-all of photography—composition printing, that is to say, pictures made up of two or more negatives. Mr. H. P. Robinson, of Tudebridge Wells, is the high priest of this particular branch of the art, and he shows all his old skill in a large composition picture entitled "Between Two Lights." Clever it undoubtedly is, though one could but wish the only figure in the picture had been better worth the trouble evidently bestowed on the work as a whole. Mr. H. Garrett Cocking, of 26, The Parade, High Road, Lee, shows some interesting genre pictures, and has a well-executed enlargement of a group taken at the house of the Rev. F. F. Statham, Vicar of St. Peter's, Walworth, and President of the South London Photographic Society. Mr. T. Fry, of Surbiton, has also some specimens of good work.

Not the least notable exhibits are the specimens of platinum printing shown by the inventor, Mr. W. Willis, jun., 2, St. Mildred's Terrace, Bromley Road, Lee. The stigma which always rests upon the ordinary photographic print is that the chloride of silver with which the picture is formed is not stable, and hence, sooner or later, the photograph must change colour or fade. Platinum prints, on the contrary, are believed to be perfectly permanent, while the working of the process may be reckoned by minutes as compared with hours in the ordinary way. The drawback is the slowness and feebleness of tone which at present make it unsuitable for portraits. For book illustration, however, it is admirably adapted. Mr. W. Cobb, of Woolwich, shows some skilful specimens of portraiture printed in platinum; and Mr. T. G. Hemery, of Hanover Street, Rye Lane, Peckham, a portrait of Mr. Glaisher, President of the Photographic Society, similarly printed. There are a number of photographs taken by the artificial luxograph light, and also by the electric light. Mr. J. Hazard, of 6, Tho, Pavement, Clapham, shows a collection of fancy dress pictures taken between ten p.m. and six a.m. on gelatine plates by luxograph, which are more noticeable from this fact and from their technical excellence than for the subjects. To say the truth, one or two are not a little absurd. This, however, may not be Mr. Hazard's fault. Mr. Vander Weyde is, we believe, the only exponent of portraits by the electric light, and some are certainly as good as they could have been had they been produced in daylight. The Autotype Company, as usual, contribute a goodly collection of their excellent work—a number of photographs on enamel being particularly noteworthy. Mr.

R. Faulkner shows some Autotype prints of his very artistic portraits of the children of the Prince of Wales, and has also some charming specimens of the powder printing process on opal. We miss the name of Mr. Valentine Blanchard, of Regent Street, from among the exhibitors. Next year we hope he will enhance the value of the Exhibition by something from his hand. The pictures, as a whole, have been well hung, and every attention to visitors in regard to explanation of processes, &c., is paid by the courteous assistant secretary, Mr. Edwin Cocking, Queen's Road, Peckham. The Exhibition remains open during the month, and on Saturdays until ten p.m.

(From FUNNY FOLKS.)

A VISIT to the Photographic Exhibition is a positive luxury. The committee, with great thoughtfulness, have provided a number of *cartes* for those making a perambulation of the room. The novelty of the Exhibition is the number of portraits on "dry plates," a feat hitherto believed to be impossible; although the art was evidently known among the Jews, as we read of the head of John the Baptist being presented to Herodias on a *dish*. Portraits on "wet plates" have nothing to do with water-colours, as some suppose; while the difference between the photographic and the dinner plate appears to be that in one case the plate, and in the other the sinner, is placed on the "rack."

The pictures by the electric light are very striking, and those by the gelatine process, from their extreme rapidity, may be described as perfectly angelactic. In fact, gelatine is now running a neck-and-neck race with collodion, and so quick has it proved in taking pictures that we should not be surprised if it "took itself off!"—a consummation no doubt devoutly wished for by the old masters, who look upon it as the Pretender in this modern battle of Collodion.

This, however, is not of the least consequence to the public, who would gladly lend their countenance to any improvement in so "taking" an art; and in the meantime, let us hope that photographers, while fiercely waging the contest, will maintain that *camara-derie* which has always distinguished them.

NOTES AND PRACTICAL SUGGESTIONS.

BY A. M. DE SILVA.*

It will soon be time again to take up in earnest landscape work; in these parts we haven't had any decent weather for landscaping worth mentioning this year; we had August weather in May—haze, haze, and nothing but haze—it being impossible to obtain anything presentable where distance was included in the pictures.

Only recently I read a paragraph praising a lens for its wondrous depth of focus, near objects, and those ever so far—miles—away, being sharply defined. That might be all very well in the particular case of the correspondent; but in a picture it is woefully inartistic. We find authority, and very good authority too,† for getting some object, animate or inanimate, as near the camera as possible, on which alone to adjust the focus, entirely discarding the distances, as one of the best means in assisting to produce a truthful stereoscopic effect of relief and aerial perspective, the want of the latter especially having constantly afforded an excuse for the enemies of our art to deny the possibility of artistic effect being produced in the camera.

"Doctors differ," and "things oftentimes work by the rule of contrary." A good deal has been, and will continue to be, written about blurring, thick films being recommended in order to reduce it to a minimum. My experience during the past winter has proved the very opposite to be the best. During the winter I have, for several years past, had occasion to make a great many interior views. Where the exposure is protracted, a thick wet film is much easier to keep than a thin one; but finding that it was impossible to obtain good definition (on which a great deal of the success of the picture depended, the rooms invariably being filled with small photographs) with the thick films, I was obliged to abandon them and return to my former method—a rather thin film, when the definition was always most perfect. My experience has been the same with dry plates; more depending on

* Philadelphia Photographer.

† R. Manners Gordon in PHOTOGRAPHIC NEWS.

the quality and the colour of the film than on the thickness. More anon.

At this season of the year, chain lightning and oyster-shell markings are the bane of photographers; they both appear on the same side of the film—the thinnest. The former appears to me to be caused by a separation of (at least a portion) the cotton and haloid salts, leaving insensitive places on the film. Sometimes a very vigorous shaking of the collodion will mend matters; but it can be effectively cured by diluting the collodion a little, and after flowing it over the plate, before pouring the surplus into the bottle, lowering the upper corner of the plate so as to allow the collodion to pass in a steady wave over the first coating. The “oyster” shell, as recommended by Mr. M. Carey Lea years ago, can be avoided, to a certain extent, by keeping the plates cool and the collodion cold, coating as rapidly as possible, and losing no time in getting them into a well kept silver bath, draining the plates carefully, and keeping clean the corners of the kits.

I had doubts as to the matching of the new back cells for portrait lenses issued so long ago by the Messrs. Voigtlander; I have recently had an opportunity of testing one. Here I might mention that the original objective and the new back cell were not sent out together; the latter (through the kindness of Messrs. Benjamin French and Co.) having been loaned to substitute for the original back cell of a portrait lens made several years ago; the equivalent focus of the lens, a No. 7, being 18.5 inches, its largest stop about one-fifth of the focal length. The focus of the new lens—that is, the front of the old combination, with the new cemented back cell (in place of the original one) measured nearly fifteen inches. It worked nicely, covering well a 6 by 8 plate with the largest stop— $f \frac{1}{4}$; the definition being perfect; the depth of focus sufficient to satisfy the most exacting. By separating the cells a little, the field was much flattened; and it would cut considerably more. Taking it altogether, it will be found a most useful attachment for those already possessing Voigtlander tubes, enabling them at half the cost to have a practically much quicker working lens, either for full-lengths or smaller pictures; while the original, on account of its longer focus, is better adapted for the large heads.

Correspondence.

HONORABLE MENTION.

SIR,—From the announcement in your last referring to awards at the photographic exhibition, I fancy someone has blundered. Will you pardon my curiosity if I ask you, or anyone else who can answer, to whom the blunder is due? Either the jury has out-stepped its instructions, or the announcement of prizes offered which appeared in your pages was imperfect. In it no allusion to awards of honourable mention was made. Was the jury empowered to award honourable mention, and was the announcement deliberately withheld? Or has the jury, with an unlimited power to award medals, of its own motion undertaken to limit the distribution of medals, and award “honourable mention?”

I ask this because I have reason to believe that “honourable mention,” as compared with a medal, is regarded by many as something like a slight: something like a pat on the back for good intention in case of failure to win a prize. To be passed over unnoticed might mean that the picture had escaped careful attention; but to be honourably mentioned implies examination and a verdict of “not good enough.”

This may be a trivial matter, but trifles make the sum of human things, and competing exhibitors feel these trifles.—Yours,
A NON-EXHIBITOR.

SIR,—I once heard a well-known photographer—I don't think he would object to having his name mentioned in this connection, it was Mr. Robinson—say that he had never

suffered the indignity of “honourable mention” but once. “But,” said he, apologetically, “it was when I was very young, and at the hands of poor foreigners who knew no better!” After taking, as I have heard, more than fifty medals at as many exhibitions, I notice that he, with some other unfortunates, of whom I am one, has again had thrust upon him this unenviable distinction. But my object in writing was not so much to point this out, as to enquire by what authority the jury appointed by the Council to award the medals at the present Exhibition of the Photographic Society gave certificates of honourable mention at all? I turn to the prospectus of the Exhibition issued by the Council, and can find no mention of other awards than medals.

The creation of distinctions in the awards is a decided and much to be deprecated departure from precedent, and is not authorized or justified by any announcement. I have heard, and always believed, that the reason why the medals are of bronze was not from any motive of paltry economy, but that there should be no invidious distinctions.

The jury of the present exhibition have gone out of their way, apparently without any good reason, to introduce for the first time an effectual method of offending some of their best exhibitors. I think it more than probable that if some of the exhibitors had been aware that they would lay themselves open to this slight, their works would not have been seen on the walls of the Gallery.

I cannot understand any photographer seeing his works gibbeted as second-rate, without a sort of feeling of shame coming over him. Total neglect I can understand and forgive, but to be selected as one of a lot to be damned with faint praise is irritating, to say the least of it. I can understand a veteran like the one I have perhaps unwarrantably mentioned, who must feel surfeited with honours, caring very little about it; but it must be very different with those who are not so over-burdened with decorations.—I am, sir, with much regret,
HONORABLY MENTIONED.

MEDALS: TO WHOM DUE?

SIR,—A discussion, an important discussion, has been commenced in your journal regarding the relative rights in a completed photograph of those who have been concerned in the result. It is a subject which I have debated in my own mind since I became practically acquainted with photography, but I never broached the subject, as I did not know what the actual state of matters was. I now find—rather, I admit, to my astonishment—that prizes are given for the actual result merely.

Without wishing in the slightest degree to detract from the merits of those who have got prizes at any exhibition, I fail to recognise the propriety of a prize being given for a photograph which is not the work—I would almost say the entire work—of the exhibitor. When do we ever hear of any painting which is the work of more than one artist? I do not believe that a landscape painting, exhibited at the Academy or any of the other galleries of art, was ever the work of more than one artist; and in portraits, while the assistants may sometimes do the drapery and accessories, the face, which is the chief point, is the entire work of the artist.

Some of the photographic portraits which may have received prizes may have been the combined result of six persons—the poser, the operator, the developer, the retoucher, the printer, and the spotter-out. I do not say—because I do not know—that any one picture has been or is necessarily the result of the combined efforts of so many; but it may have been. To whom of all these is the meed of honour due? Perhaps not one of them gets it; but it may be given to an exhibitor who may have been merely the employer of all these co-operators.

Let photographs plainly state whether they are combination photographs, or the actual work (up to the printing stage, at least) of one man, and then the profession and the public can judge of the real merits, not only of every individual picture, but also of every individual photographer.—Yours obediently,
A. Z.

FRILLING IN GELATINE NEGATIVES.

SIR,—Having cured some very obstinate cases of frilling in gelatine negatives by the use of chrome-alum in the alkaline developer, I recommend it to such of my friends as may have any troubles in that direction. The proportion to be used varies from $\frac{1}{2}$ to $1\frac{1}{2}$ grain per ounce. It is also of use with Mr. Henderson's new developer. I greatly prefer either of the above to the oxalate developer, which has no latitude in its use, and negatives from which I have found to stain terribly after printing. The best varnish for gelatine negatives I find to be Hopkin and Williams' crystal varnish, with (if very much printing is necessary) a coating of shellac varnish over it.

I would advise those who intensify with mercury to avoid an excess of iodide in using the mixed solution, and to pass the negatives after intensification through a weak bath of hyposulphite of soda. Many negatives treated thus by me in 1861-62 are still in perfect order.—Faithfully yours,
H. STUART WORTLEY.

Talk in the Studio.

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.—The *Times* says:—"In our notice of this exhibition we remarked that although the Royal Engineers appeared among the exhibitors there was an entire absence of views of a military character. Since our article was written this want has to a certain extent been supplied; a fine series of photographs taken by the Royal Engineers in the neighbourhood of Jollalabad and the Khyber Pass can now be seen there, and these views give a good notion of the real character of the country traversed by our troops."

COLLODION IN SURGERY.—"An interesting surgical case," says *Nature*, "was recently reported by M. Larrey to the French Academy of Medicine. A young carpenter received a blow from an axe on his right foot. The big toe was almost completely detached; it was held merely by a small thread of skin, and hung on the side of the foot. Dr. Gavey, who was at once called in, detached the toe completely, then after having washed it and the wound on the foot, he adapted the two surfaces as well as possible one to the other, and made them hold together by means of strips of lint soaked with collodion and placed along the toe. When the collodion had set, another strip was wound round. Further, an apparatus was used to keep all the parts of the foot in perfect immobility. Twelve days after, the dressing gave no bad smell, the patient was very well, and desired to go out, and twenty-four days after the accident the cicatrization was perfect."

PHOTOGRAPHS FOR ROGUES' GALLERIES.—Mr. Luke Fildes' well-known cartoon of "The Bashful Sittor," the sturdy jail-bird who violently resists the operation of being focussed by the photographing warder, and is consequently held down by main force in front of the camera, has found a curious reduplication in real life. There is under detention in Newgate, on a very serious charge, one Ambrose Fortescue, an American. It occurred to the usually judicious governor of Newgate that the interests of justice might be served if the police could be put in possession of a portrait of Fortescue, who was accordingly ordered to stand at attention to be photographed. The American, however, preferred to stand on his rights as an untried prisoner, and flatly refused to be photographed. Thereupon the governor, forgetting that he was dealing with an unconvinced prisoner, ordered the man to be seized and photographed against his will. Against this illegally high-handed proceeding the prisoner protested, and Mr. Callan, on Monday, interpellated the Home Secretary on the subject. Mr. Cress very promptly and candidly replied that the governor of Newgate had acted entirely against the rules in this matter, and that the Prison Commissioners, having had the circumstances brought under their notice, had expressed their disapproval of what had been done. Care will be taken, added Mr. Cress, to prevent the recurrence of such an irregularity. The charge against Fortescue being still *sub judice*, it cannot obviously be commented upon; but, should he get a good deliverance, he may be advised that an action will lie against Mr. Sidney Smith for assault and battery, in causing him to be photographed against his will.—*London Telegraph*.

To Correspondents.

B. REVEX (Haute Saone).—The cause of the serious fading of the portion of print enclosed we should regard as due to imperfect fixation. The hypo fixing bath has been too weak, and it is probable that it was employed to fix too many prints, and was probably acid. The germs of decay were doubtless left in the print when it left the hypo bath. As a rule, the fixing bath should contain 25 per cent. of hypo, and should not be used at a temperature of less than 60° Fah. It is possible that the green card may have facilitated the change; but whether it contained anything injurious could only be ascertained by analysis. 2. We do not know the precise formula used in toning by the gentleman in question, but we should think it was probably the acetate bath. The element of chief importance in obtaining such tones is the possession of a brilliant intense negative which admits of deep printing. With a deep print from a good negative almost any toning bath will give rich tones. The effect of the tone is much increased by mounting the print in contact with the glass. 3. For a short preservation the use of carbonate of soda appears to us to be best as described by Mr. Hopkins.

SOUTH DEVON.—We have not made comparative trial of all the commercial gelatine plates, and could scarcely undertake the responsibility of saying which was best if we had. Of those named in your list we have heard best accounts of No 3, and next of No 5.

C. B. (Bath).—We regret that we cannot give you the requisite information to enable you to construct a changing-box. We are not very familiar with the mechanical details of the construction of apparatus; nor, however familiar, could such instructions be clearly conveyed without the aid of diagrams. As a rule, such apparatus, to be of any use, must be made by a professional manufacturer. So also of the walking stick stand.

A CONSTANT READER.—We fear that we cannot give you a certain opinion as to the value of the apparatus you describe, all of which is quite obsolete. We give you advice as to how to get some idea of the value more trustworthy than an individual opinion. Write to Mr. Morley, of Islington, to Messrs. Hunter and Sand's, or any other second-hand dealers, and ask what they will give for the apparatus; or get their catalogues and see at what price they offer similar old-fashioned apparatus. Voightlander, for a long time after English makers had adopted the improved style, made lenses not coincident in visual and chemical foci. This defect may largely be got over by care, but it is a perpetual source of trouble. We should think that the lens might be used for portraiture, but its quickness can best be ascertained by trial.

MIDDLE.—Your simplest plan would be to throw the solution amongst your residues, and make a new one. If, however, you are anxious to try the permanganate, proceed as follows:—The bath to be treated should be turned out into a beaker or bottle, and a drachm of a 10-grain solution of permanganate of potash to a pint of nitrate bath added, the solution being then agitated. If the pink colour rapidly disappears, a little more may be cautiously added; and when a faint tinge of the pink or purple colour remains, the solution should be set aside for a few hours to allow the reaction time for completion. It is not necessary to go on adding permanganate till all trace of the smell of alcohol is removed, as a portion of that body may be present without producing injurious results. A chocolate-coloured deposit of binoxide of manganese, and, probably, a little permanganate of silver, will be thrown down if excess be added, and the bath will be weakened. It should be remembered, however, that the strength of a solution as ascertained by its specific gravity is not very accurately indicated after treatment of this kind.

BEGINNER.—As a beginner, learn to rely upon care and artistic taste more than upon special formula. The developer used by M. Adam Salomon, about which you enquire, is as follows:—

Ammonia sulphate of iron	75 grains
Glacial acetic acid	75 minims
Sulphate of copper	7 grains
Water	3 ounces

N. P.—We consider Captain Abney's Instructions in Photography to be one of the best manuals we have, superseding that to which you refer, both in scientific information and practical value. 2. The meaning of the term six inches focus in a lens is that it will give a sharp image of the sun, or any object at a very great distance, upon a focussing screen placed six inches behind the lens: What is termed the "solar focus" is that which gives the nominal focus to a lens. For near objects, of course, the focus gradually lengthens.

P. Q. R.—A method of using moist collodion emulsion giving reasonably rapid results was described in our pages two or three weeks ago on p. 477.

Several correspondents in our next.

The Photographic News, October 31, 1879

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

WHAT ARE OBSCENE PHOTOGRAPHS?—THE NEW COLLOID COPYING FILMS—MAYLAND'S MARVELLOUS MONKEYS.

What are Obscene Photographs?—It is surely high time we came to some understanding upon the question of what is an obscene photograph. At present, so far as we can understand, it suffices for any detective to declare that a photograph is obscene, and report that it is so, in his judgment, to a magistrate, in order that a warrant may issue for the imprisonment of publisher or seller. It is not a question of a summons. Mr. Phillpott, who was before the Lord Mayor recently for selling obscene prints, may deem himself fortunate that he was not taken up on a warrant. It was quite out of the usual course to issue a summons. A policeman holds some photographs of Zulus to be obscene, and, as soon as a policeman thinks so, this is enough to bring Lord Campbell's Act into motion, and a warrant is issued. You call a dog a bad name, and then hang him. Very fortunately, in this case, the Stereoscopic Company are the publishers, and therefore we shall have the case decided on its merits. It would have been very unsatisfactory indeed if the course suggested by Mr. Phillpotts' counsel had been adopted, namely, to destroy the pictures, and withdraw the summons. If the photographs are truly obscene, let the law take its course, by all means, whether the Stereoscopic Company or other respectable firm is at fault; but if they are not, for goodness sake let us be told so, and an end made to the apparently absurd proceedings. We have all heard of the young American lady who put the naked legs of her piano in white frill trousers, to prevent visitors from being shocked, and no doubt there are people who would desire to see the Zulus provided with a garment or two in the photographs. Unfortunately, clothing does not always suggest decency; on the contrary, it is almost impossible, we hold, to have obscenity with absolutely nude figures. It is just the scanty clothing that frequently makes all the difference. We have no desire to say one word in countenance of even doubtful photographs, and, with every right-minded person, must express our unqualified satisfaction at the prosecution of producers and sellers of filth; but we must be excused if we hesitate to accept the opinion of a policeman as to what is obscene and what is not. We will go further, and say, that the way in which detectives appear to get up evidence in connection with these matters is very open to question. There is not a painter, draughtsman, or photographer, who has not produced work, at one time or another, which some of these men would not have the presumption to call indecent. Sometimes, even, it appears, that they importune and worry photographers until the latter, in a weak moment, at last part with pictures that should never go into the hands of others but art-students, and by this transparent trick they attempt to get a conviction. Sometimes we find Custom-house officers taking upon themselves the duty of judging between art and obscenity, and condemning as indecent work which has received the highest encomiums from artists. As if there could possibly be any doubt between an art study and an obscene print to the ordinary mind! But there is a difference between the Customs and the Police. The policeman, when he has been employed as a detective, has no longer an ordinary mind, and is apt to see a lurking crime in everything; thus it would be little use to attempt to enter into the intricacies of his thought, and to find out why and wherefore he considers a picture indecent. But the Custom-house officer, in his opinions, is more frank and intelligible. With him, obscenity in a picture is easily defined. All studies of the nude are with him indecent; that is the hard and fast line he draws, and many photographs of classic paintings of the German and French school are stopped by our Customs on the ground of

absence of clothing. It is not so long ago that a most ludicrous instance of art studies being stopped by the Customs came under our notice. The pictures were photographs taken by the late Mr. O. G. Rejlander, who was engaged, as our readers know, in making the studies time after time for painters. He had an order for upwards of a hundred such studies for India, prints from negatives which had been printed over and over again in the country, and the prints distributed. Mr. Rejlander was very ill at the time; but the pictures were selected, packed, and sent off. His death followed before the prints arrived at their destination, and his widow, a few months after his decease, received an insulting note from the Calcutta authorities, stating that the photographs had been seized and condemned. Some portion of them, indeed, had been destroyed by the clever officials, who had doubtless gloated over the studies until their own prurient minds had warped their judgment; but the rest were kept awhile in order to see what their consigner had to say for himself. Mrs. Rejlander came to us in great tribulation at the circumstance, and begged assistance in the matter. Luckily the proof of the genuine character of the sketches was not difficult to furnish, and we at once wrote to Major Waterhouse, the Deputy Surveyor-General of India, requesting his kindly influence in the matter. Every picture bore the familiar initials of O. G. R., and we were so fortunate as to have in our possession at the time a list of the subscribers to the Rejlander Memorial Fund which was started soon after our friend's death. This list of subscribers we enclosed to Major Waterhouse, so that the Calcutta authorities might have some idea of the estimation in which Mr. Rejlander and his works was held in this country. That list, we remember, contained the names of half-a-dozen ladies of title well known in the art-world, noblemen and gentlemen who were artists and painters, an archbishop, and was headed by one whose name is familiar as the founder and proprietor of the Grosvenor Gallery. The Calcutta authorities did not stand out after Major Waterhouse's representations, and we have to thank that gentleman for vindicating the name and honour of a dead brother. In London, the professional guardians of our morals seem lately to have got into the same way of thinking as the Calcutta gentlemen, and hence we say it is high time that we should come to an understanding as to what is an obscene picture. But we protest against any policeman or detective being appointed judge of such matters, and upon the issue of a warrant on the sole testimony of such an official.

The New Colloid Copying Films.—A hundred and one copying processes have suddenly been thrust into notice by our stationers and booksellers. They are, for the most part, variations of one and the same thing. You write with aniline dye upon paper, and this is pressed against the colloid film. This colloid film will then print off any number of copies, more or less, upon other paper pressed against it. Enthusiasts talk of a hundred perfect copies; but as you cannot get off more ink or dye from the film than you have put upon it, the number of copies depends upon the density of the dye first applied. The dye is dissolved in alcohol, and as the tacky gelatine (a mixture of gelatine and glycerine will answer the purposes of a printing block very well) will not absorb alcohol, it stands to reason that the dye remains upon the surface of the film, and comes off readily upon the paper hereafter pressed upon it. If a number of rough copies of one document is required, this method of copying may be useful, but at best the result is not better than a bad lithograph. A bottle of Judson's dye does very well for ink, the violet being best, as it is the strongest, and yields most copies.

Mayland's Marvellous Monkeys.—We see that Mr. Mayland is continually asking the question in these columns, whether we have seen his marvellous monkeys. We certainly have; but not at the Exhibition, where they ought to have been. 'The marvellous monkeys in question would

have made capital companion pictures to the fine animal studies that adorn the end of the room in Pall Mall, and are among the finest exhibits of this year. It is a pity, therefore, that Mr. Mayland did not think of sending his pictures, which would, moreover, have added one proof the more of the efficacy of gelatine plates. The strong point, however, in Mr. Mayland's monkey pictures is the quaint humour of the sitters. We have a monkey—Arabella Goddard—rattling over the keys of the piano in ecstatic delight, and we have the same monkey abandoning himself to low tastes and drink, represented with an empty beer-jug in his hand, in a low pot-house. "Studies of Character" would be a good title for Mr. Mayland's marvellous monkeys, and we hope that gentleman will forgive us saying that his models, clever as they are, appear more familiar with low life than high life; but, perhaps, we can hardly expect such lofty ideas to be floating through a monkey's brain, at the time it is photographed, as are to be found in human heads—say, of professional beauties.

FRENCH CORRESPONDENCE.

PHOTOGRAPHY AT THE NATIONAL CELEBRATION OF THE INDEPENDENCE OF BELGIUM, 1880.

If anything were wanting to prove that the young state of Belgium has attained the period of adolescence, it would most surely be demonstrated by the ardour and enthusiasm with which the inhabitants of that country are making the necessary preparations for the national *fêtes* with which are to be celebrated the fiftieth anniversary of the foundation of the ruling dynasty. More especially at Brussels the organisation and arrangements of these *fêtes* are creating great excitement, and appeals have been made to all the Associations of art, commerce, and manufactures, to lend their aid in promoting the good cause. Photography will be required to play a prominent part at the celebration, as, indeed, is already manifest, although a whole year still intervenes between the present and the date of the *fêtes*, which are fixed for the month of September, 1880. The Special Commission charged with the various arrangements has been for some time in full working order, and they intend soon calling on the photographers to render all possible assistance in furtherance of their plans. It is intended to form a sort of Pantheon, where will be exhibited portraits of all the illustrious men to whom Belgium has given birth, as well as representations of their best known works; also illustrations of all the great undertakings—whether due to private enterprise or to the energy of public departments—which have been brought out since the separate kingdom was established in 1830. Although the country is a small one, a very large space would not be sufficient to contain all its works of art and science; architecture, painting, sculpture, manufacturing industries, organisations for the promotion of agriculture, and charitable institutions, are all so many innumerable monuments of the vital and productive forces of the nation which can only be represented at this Pantheon by faithful reproductions. Here, then, photography will come into play; our art will be able at least to serve as a guide to the decorative artist, even if it be not required itself to produce pictures for filling up gaps in the marvellous show which it is proposed to form.

It is, therefore, easy to foresee the importance of the official rôle which photography will be called on to fill in this national celebration; but the part which the art in its private capacity is capable of playing seems to be no less important, and it may, perhaps, be of service to point out this fact. Operators who are strangers to the country may possibly entertain the idea of doing something to add to the success of the Belgium celebration, or of collecting and distributing photographs which will serve as reminiscences of it. There is so much to be done in this direction that the native photographers will scarcely find their interests

injured by a foreign art speculation. It can but create healthy rivalry in the production of albums containing views of churches and public buildings, and copies of the pictures in public and private museums, and in their sale to the numerous strangers who will flock to this artistic corner of the world to see it arrayed in holiday garments, and proud of its triumph and the trophies of its success. The fervour of patriotism may be relied on not to leave unknown the smallest of the glories of Belgium.

All the societies and clubs in this country are desirous of offering to the Royal Family of Belgium some *souvenir* of the fiftieth anniversary of the foundation of the dynasty, and many ideas and plans have been entertained. Eventually the majority have decided to present to their sovereign a series of richly-bound albums containing the portraits of all the members of these associations. Those who know how largely the club-spirit is developed in Belgium will be able to form an idea of the enormous weight of paper, cards, and binding which King Leopold II. and his august family will be asked to accept; there is also reason for supposing that they will never be able to find the time to examine all these loyal and affectionate offerings.

As regards private enterprise, the house of Ghemar Bros., of Brussels, always distinguished for energy and ability, has been the first to make preparations for the coming event. Of course, their position as Court Photographers offers to Messrs. Ghemar an opportunity of carrying out successfully undertakings which other houses might find it impossible to enter on. Thus in a very short time they have already produced an album containing the portraits of all the ministers, senators, and deputies of the Belgian Parliament, and this will, on the occasion of the National Celebration, be presented to the members of the Royal Family. Meanwhile, however, the collection of portraits of all the political celebrities of the country may be regarded as published, and the public may select and purchase any of these portraits they may wish for without fear of discovering the secret. Taking the recipient by surprise is generally considered to be an essential element in making a present, but it does not appear to be necessary in the case of crowned heads.

The ingenuity of Messrs. Ghémar, however, has not stopped short at this point; they have hit on and are putting into execution a most original idea, though no one will be surprised on that account, for they have always had the credit of a monopoly in eccentric productions. It will be in the recollection of my readers that Messrs. Ghemar themselves, excellent draughtsmen and caricaturists, have been the means of drawing public attention to the greater number of celebrated pictures of our age, and have for a long time maintained an exhibition of artistic fancies, many of which have been reproduced by photography. The Belgian public, accustomed as they are to the whimsical and eccentric though lucrative enterprises of Messrs. Ghemar, have learned without astonishment that their latest idea has been to invite all burgomasters of the country to come and have their portraits taken, with the object of forming an album of all the principal communal magistrates, which is also to be offered to the king on the occasion of the National Celebration of 1880. The proposition has met with general acceptance; it is held to be an excellent idea to present to the head of the nation a collection of all the civil officers whom he has appointed, and who may be held to represent the real popular opinion of the country. In Belgium, the chief authority in the commune is a council elected by the citizens, and the burgomaster, or mayor, is always selected by the king from among the councillors thus elected.

No doubt the burgomasters are much obliged to MM. Ghemar, and it is to be hoped that MM. Ghemar will be equally pleased with the burgomasters. It must also be remembered—and the wily photographers have probably not

lost sight of the fact—that the burgomaster is surrounded by a bevy of communal councillors and faithful dependents, who will be eager to possess a portrait of their chief. Besides, there are the members of his family who will all be anxious to have a photograph of their respected relation, "taken at Brussels expressly for His Majesty." The sale of copies of the photographic portraits will, therefore, probably be large, so that Messrs. Ghemar, having hit on a highly patriotic idea, and having carried it out at their own expense, may at the same time have entered on a successful commercial speculation. This excellent plan may be recommended to the notice of the photographic contractors of larger countries, who, perhaps, may be enchanted to work it out on a large scale if an occasion presents itself. Once the idea is given, there will, no doubt, be an opportunity to put it into practice at any one of the commemorative celebrations which are now so common, and if there are no burgomasters there will surely be some other class of public functionaries who will like to have their portraits presented to the Chief of the State.

K. VERSNAEYEN.

ON WASHING SILVER PRINTS.

BY J. E. WALKER.

EVERY photographer knows the value of removing every trace of hyposulphate of soda from the prints immediately after removing them from the fixing bath; and that the process by which this is done should be as simple and efficient as possible, will be acknowledged by all.

The process that I am about to describe is, I think, as simple, and also as rapid, as anything that has been invented. It may not be new to some, but, as I have never seen it in print, I venture to give it to the photographic world, believing that it will be well worth a trial. First, procure a wood box or bath, say about twenty inches by sixteen (with glass bottom preferable), and about four inches deep; make a series of round holes about half an inch hole all round, and about an inch from the top, which are to allow the waste water to overflow as the trough gets full; set it into a large sink and under a tap, to which attach a short piece of india-rubber tubing; on the other end of the tube, and within a few inches of the top of the trough, fix what is known as a "rose" (they are used by fishmongers to rinse the fish on their slabs, and consist of a bell-shaped tin end perforated all over with small holes); these, when the tap is turned on, send a shower of water all over the prints, which are placed in the shallow trough underneath it (these small streams of water are similar to a good shower of rain). When the prints are washed enough, they can be removed, and the washing trough may then be put away until wanted again. It can also be used for fixing the prints in if required, but it is better to have a separate dish for this purpose only. The above will be found easy to make, and inexpensive, and requires no attention when in use, as when the water is started it rises and overflows through the holes round the box into the sink, thus being self-acting. I have seen many different arrangements for washing prints, but I think the above method will be found most easy of any.

A PHOTOGRAPHIC NIGHTMARE.

BY W. G. SHAW.

To be, or not to be, that's the question. Whether 'tis better in the NEWS to enter a vision of the night, or to pursue the even tenor of one's way rejoicing in dry plates and short exposures. Lest my dream may prove of value to "some forlorn and weary brother" whose studio is besieged by the juvenile community, and who, on reading, may take heart again, I put aside my natural reserve and reticence, in the cause of photographic humanity.

Methought the day was dull and the hour late, when a cabinet group demanded my exertions. Their number

appeared about six all told, but for some reason (what, I cannot tell) one urehin ran about so, that, like Paddy's pig, I never could reckon him up.

This brat, imp, or hoy, was the genus which developed a dream, until it became a positive nightmare, so intense did my anxiety become to secure the young rascal. All could he got but him. A happy thought at last came to the rescue: a dry plate with a few extra drops of ammonia in the developer—yes, hound to get him now—and I awoke with a feeling of supreme thankfulness to Mr. Swan in particular, and all good dry-plate manufacturers in general, for the ease, comfort, and certainty with which an operator can now perform his daily duties.

Much is written about the development of emulsion plates, and as an aid towards successful working and help in emergencies, it is well to observe the experiences of different workers. In this, as in all photographic formulas, it is scarcely possible for every one to succeed alike with the same formula, but every operator must have some idea of the general principles, or his success will become mere chance. I have long since discarded the oxalate method. Doubtless some will think it perfection, and in their hands it yields fine results; but to me it was verily a "weariness to the flesh." The length of time it took to develop, except when quite fresh, was a great drawback. My practice being almost exclusively confined to portraiture, time is of vital importance.

The pyro formula published on Swan's instructions with slight modifications I find work perfectly. To be explicit, I make two solutions as follows:—

No. 1.—Pyro 20 to 30 grains
Rain (not common) water 10 ounces

By increasing the strength of this solution greater intensity is obtained.

No. 2.—Liquid ammonia ¼ ounce
Bromide ammonia 1 drachm
Water 10 ounces

Mix equal proportions of each solution and flow over the plate, which is of course placed in a flat dish. To be a really good negative it should develop as readily as a properly exposed wet plate. Should it not do so, have at hand a solution of ammonia, one part to one part water, and add a few drops, taking care not to add too many, nor in such a manner that it acts unevenly upon the negative. Observation and experience will soon teach when to add and when to refrain from adding. To check too rapid development caused by over-exposure, a solution of—

Bromide 1 part
Water 2 parts

added in the same manner, is extremely useful, although it is best to endeavour to obtain the correct time.

Regarding intensity, proper development (if exposure is right) will always secure sufficient density; but should the negative while developing appear to lack vigour, add a little (say 1 drachm) of the pyro solution, which invariably puts it right if done in time.

In my early attempts I was plagued terribly by round spots, apparently lumps, but which I found to be due to air-bubbles upon the plate under the surface of the developing solution. These will cause no end of mischief, and if the manipulations are not carefully executed will prove extremely annoying.

Mr. Swan says the pyro solution should be mixed about two hours before using. This may be so, but in my experience I find it work just as well, and sometimes better, three or even four days old, while the hypo used a week works clean and good; certainly, I keep the pyro solution in the dark room, but take no more care of it.

Waiting for negatives to dry when copies are required in a hurry is a little tedious; the spirit flooding greatly accelerates drying, especially if the negatives are put in a rack near an open window. Retouching without varnishing is at first somewhat troublesome, but practice will soon overcome this difficulty.

No one who has once overcome the few primary difficulties of rapid dry plates, and began to work them successfully, will be content to return to the old wet process. When sitters speak in eulogistic terms of such short exposures, and praise the perfect portraits of their little ones, it will indeed be only the "old fogies" who will not yield to the advance of chemical science as applied to photographic art.

PHOTOGRAPHY AND LIBEL.

The action against *Town Talk* for libelling Mr. and Mrs. Langtry and Mrs. Cornwallis West was recently heard at the Central Criminal Court. After going through the evidence, the chief part of which we have already published, Mr. Watkin Williams, on behalf of Mrs. West, said:—

The libel upon Mr. and Mrs. West which appeared in *Town Talk* was not a "mere burlesque," but a most serious and grave libel. Mr. West is the Lord Lieutenant of the county of Denbigh and a magistrate holding a high public position. He and his wife live, and have lived, with their children in the district for years, beloved and respected by their neighbours. Mr. West and his family have a mansion at 49, Eaton Place, London, and they live there in the season. Of late years, since the photographic art has developed itself with such perfection, a large number of artists and photographers have—in the legitimate exercise of their trade—pushed it to an extent which is, perhaps, to be regretted. Almost all persons who occupy any position at all—who are conspicuous in society, in rank, in professional eminence in the Senate—are now inundated with applications by artists to have the distinguished honour of taking their portraits, and so on. When that started, probably nobody thought very much of it; but by degrees this became a nuisance. In the case of women, they began to discover to their annoyance that their photographs were beginning to be spread over the town. I propose to show your lordship with regard to this that a misconception and a mistake has arisen as to the power of persons to stop the publication. I can show you that any one who has his portrait taken has no power whatever to prevent the photographer from publishing the photograph. In this case Mr. West more than a year ago took steps to stop the publication of these photographs. He consulted me about it, and I told him then, as I tell him now, that he has no power to stop it.

Mr. Justice HAWKINS.—That is to say that when a bad photographer sends out a hideous deformity as your portrait you are bound to let it go.

Mr. W. WILLIAMS.—I mean to say that the copyright is in the photographer. By a strange error in the report of the commissioners on copyright, the words of the Act of Parliament are left out. Mr. West took every step in his power to prevent the photograph of Mrs. West being published.

The learned counsel then read the libel complained of, which has appeared before, and proceeded to refer to the state of the law, to show that Mr. West had not the power to stop the publication of the photographs.

Mr. Justice HAWKINS, interposing, said he would not pronounce upon that law then. He thought it was sufficient for Mr. Williams to have said that he advised Mr. West that he could not stop the publication.

Mr. W. WILLIAMS.—Mr. West did take steps to stop the publication, but some of the photographers being advised as to what the law was, declined to discontinue it.

Mr. Justice HAWKINS.—The only way to stop the publication in future is for the person photographed to purchase the negative itself.

A verdict of guilty having been returned,

Mr. Justice HAWKINS subsequently passed sentence. After some stringent observations on the enormity and persistency of the offence, he said: Therefore, for the offence of which you have been found guilty, in publishing, knowing them to be false, those libels on Mr. and Mrs. Langtry, I sentence you to be imprisoned for eighteen calendar months, and I further direct that at the expiration of that time you enter into your own recognizances in the sum of £1,000 to keep the peace and be of good behaviour towards Her Majesty and all her liege subjects for the further term of eighteen calendar months. So much for the indictment which is preferred at the suit of Mrs. Langtry. As regards the indictment preferred as affecting

Lord Lonsborough I sentence you for that to be imprisoned for six calendar months. That will run concurrently. I come now to the libel upon Mr. and Mrs. Cornwallis West. Their case stands upon a very different footing. You do not charge in the libel to which you have pleaded guilty that they were guilty of actual immorality. You did not make that charge, for you thought probably that having had six consecutive weeks of the divorce of Mr. Langtry you must vary the food you offer to your readers; therefore, you thought fit to hold Mrs. Cornwallis West up to contempt and ridicule, and make her appear a wanton, foolish, and immodest woman, who thought proper to have her photographs taken and placed along with half-nude persons in shop-windows. And this statement you thought proper to accompany with a description of her inner life, with such detailed circumstances that it would not be surprising if some persons were to say, "Can all this be untrue? Here are all these details. Can any man have the impudence and the audacity to publish such libels as these?" Let me tell you, and in telling you let me tell all those who may be interested to know it, that it is just as much a libel to hold a man or woman up to ridicule as to make imputations against the moral character of the individual. No man has a right to hold another up to ridicule and scorn, and if he does publish that which tends to bring another into ridicule he is amenable to the criminal law of the country. For this I pass upon you the sentence of six months' imprisonment, to run concurrently with the other sentences. The effect of my judgment is that for the libels of which you have been convicted you will be imprisoned for eighteen calendar months; and I only regret that I have not the power to add hard labour.

NOTES AND PRACTICAL SUGGESTIONS.

BY A. M. DE SILVA.*

SOME three years ago, in *Anthony's Bulletin*, I described the singularly rapid fading of some prints which had hitherto stood well, until they were wetted. I have also some prints made at the same time, on a different brand of paper, which are (with the exception of being slightly discoloured by time, ten years having elapsed since they were made) still in excellent condition. I divided several of them into four, damping them—nay, soaking them in water for ten minutes at a time—many times during the past three years, and still they do not fade. Why should the two samples of prints, made at the same time, from the same negatives, act so differently? They were both made on Rive paper, but the albumenizing was widely different. The albumenizer of the paper on which the lasting prints were made—the late Mr. Spencer, of London—at that time rather prided himself on using fresh albumen; those which faded "every time" were made on stinking stuff, rotten at the start. I am not alone in the conviction that stale albumen (necessary where the paper is twice coated) has a good deal to do with the fading of the proofs. I myself fail to see the great superiority of "double stinking" over the "single fresh." It is claimed that the delicacy of shadows is much better rendered; that the print "presents a much more beautiful appearance." Now, using well-albumenized paper, with a burnisher or hot press, they can be shined up—this being the idea of the beautiful with the vulgar mind—to any extent, which process will give additional transparency to the shadows. For larger work, undoubtedly the less glossy presents the most artistic appearance.

We have all sorts of remedies for blisters, and still they come, and never again adhere to the paper support; for once the albuminous coating separates from the paper support, it does not again adhere to it. If any one doubts this, let him bend inwards a mounted print which has blistered, and the larger blisters will at once show on the surface. If the prints do not blister in the hypo—and I have seen them show signs in the toning bath—very strong fresh salt and water will mend matters. But as they start generally—

* Continued from p. 515.

better, make their appearance—in the hypo, we must commence before this, in order to prevent them.

Perhaps the result of some experiments I have recently made will not be out of place here, and possibly enable others to steer clear of some difficulties. In every case I used Cross-Sword Double Albumenized Rive paper, both eight and ten kilo., the latter being the weight generally used here. On a strong bath for the paper as salted, sixty grains to the ounce, drawn over a rod, both just neutral, the prints bronzed badly; felt suspicious in toning bath (of sal soda and salt and gold), and blisters appeared in the hypo, 1 to 12, which produced murky prints. Longer fuming occasioned larger blisters; and when this was done, and the prints were placed in the first washing water, acidulated with acetic acid, the prints felt decidedly rough in the toning, were covered with small blisters in the hypo (kept weak still, and at a normal temperature); passed for several minutes through the salt solution, which was gradually diluted in the wash-tank. They were one magnificent crop of blisters—worthless! Forty-grain bath, showing the slightest acid reaction, short fuming—just sufficient to produce reddish-purple tint on print; less bronzing; prints not looking quite so bright as with longer fuming, but toned brilliantly in a bath of salt and gold, to which was added a very small quantity of bicarbonate of soda; fixed in hypo, 1 to 8; very few tiny blisters making their appearance in the hypo. Bright prints.

Two baths, as recommended by Mr. H. T. Anthony, a stronger and a weak one, nearly neutral, the paper being drawn across a glass rod, short fuming; no acid wash; toning and fixing as before. Result: no injurious bronzing, no blistering. Try it.

Correspondence.

MR. GALE'S "SWALLOW."

SIR,—The Editor of your Liverpool contemporary expresses his belief in the genuineness of Mr. Gale's Swallow: that is, that the bird, the reflection in the water, and the landscape were taken at the same time, on the same plate, in the same fraction of a second, being, in fact, to quote your contemporary's own words, "simply a *bona fide* instantaneous exposure." It would be very interesting to many of your readers to know if this is really true. For my part, I doubt it extremely, and cannot help thinking your contemporary is as credulous as the outside and this year more than usually ignorant press. I have always given Mr. Gale credit for more cleverness and skill than what would be implied by a mere accident happening to him, as, of course, the chances are many millions to one that a swallow should fly over exactly the right place in that small space of time during which Mr. Gale was exposing his plate.

The famous "Gull" picture of some years ago was never, I believe, given to the world by its author as a genuine instantaneous picture, although it was claimed as such by some of the writers on the subject. As far as I remember, it was put forward only as something for photographers to puzzle over. Will Mr. Gale inform us if he intends something of the same kind, or whether his pretty little picture is really a genuine "accident?"

INQUIRER.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

DEAR SIR,—Will you kindly permit me through your columns to announce that the Annual Technical Exhibition of the above Society will take place on Thursday next, November 6th, at the Society of Arts, Adelphi, when the committee will be pleased to see as many of the profession as can be present. I may state that the "Platinotype Process" will be demonstrated by Mr. W. Brooks; the "Luxograph Apparatus" will be worked; Mr. L. Warnerke will exhibit

Mons. Vidal's new camera; and exhibits by Messrs. Cowan, Ayres, Harrison, Auckland, and others will be shown. The chair will be taken at 7.30. Mr. Jabez Hughes has kindly consented to act as Technical Explainer.

May I also remind your readers that the Annual Dinner is fixed for Saturday, November 8th, at the Cafe Royal, Regent Street. Any further particulars of both these meetings I shall be happy to supply.—Yours faithfully,

H. GARRETT COCKING, Hon. Sec.

26, The Parade, High Road, Lee, S.E.

CAUSE OF THIN IMAGES ON DRY PLATES.

SIR,—Frequent complaints are made of the thin images resisting intensifying often got on dry plates. I believe the main cause of this is the use of German pyrogallic acid instead of English. The difference of price is considerable in money, but the English develops up a far more vigorous printing negative with a smaller quantity of developer than the other, and in the end is cheaper.

I some time since suspected the same thing, and caused an analysis to be made, with the result of being assured the English and German were identical for all practical purposes. But further experience convinces me it is far better to use English, and that it forms a complete remedy for thin, poor images.

Will some of your correspondents kindly report experience.—Faithfully yours,

SAMUEL FBX.

THE AWARDS OF THE JUDGES AT THE PHOTOGRAPHIC EXHIBITION.

SIR,—Your comments, and those of your correspondents, upon the above awards, open this very great question for thought, viz.: How far is it desirable to recognize the exhibits which are notoriously produced upon plates prepared by others than the exhibitors, and the prints also? When we observe how large a proportion of the recent prizes go to exhibitors of this character, one cannot but think that the whole question of awards and medals requires revision.—Yours, &c.,

A NON-EXHIBITOR.

SIR,—There are other matters beside the medal awards to give occasion for grave dissatisfaction with the Council of the Photographic Society of Great Britain. In their notice of the holding of the Exhibition they stated that no pictures would be received after a certain day. To my own knowledge this deterred one person from exhibiting whose picture, from various causes, was not ready until the day before the date given as the last day for receiving. Trusting to the statement in the notice, he made no attempt to get the picture off, knowing that it would not arrive in time. Notwithstanding, the Council received and hung several pictures after the day in question.

As regards myself, I have refrained from exhibiting since the objectionable rule was framed of charging non-members for space. As I am an amateur I have no pecuniary advantage to gain by exhibiting, and I decidedly object to pay for the amusement and gratification of others; in addition to which I believe in certain favoured cases the rule has not been put in force. With a Council playing fast and loose in this manner it is not my intention to exhibit again. Very many old exhibitors have been absent from the walls during the last two or three years, and I predict that fewer pictures will be exhibited in future years than even there were this year; for it did not require an expert to perceive that the exhibits were terribly spread out.

As to whether photography has made any strides in the direction of "rapidity" within the last twenty years may perhaps form the subject (with your permission) of another letter.—I am, dear sir, your faithfully,

JOHN VAUGHAN.

PHOTOGRAPHY AND INDECENCY.

PHOTOGRAPHY has figured in the Courts very considerably of late, and amongst other things it has given the British public the edifying spectacle of a Lord Mayor being called upon to legislate on a question of art decency. Mr. Phillpott, a bookseller in the City, was summoned before the Lord Mayor and charged with exposing in his window obscene photographs, the said photographs being portraits of semi-nude Zulus. The defendant said that he purchased the prints of a respectable firm—the London Stereoscopic Company—which was under the control of Mr. Alderman Nottage, and he did not think it probable they would sell anything indecent. Most people would be of the defendant's opinion, especially when he added that these were simply Zulus in their native attire. Now it may be admitted that a Zulu in that state of nudity which he considers full dress is rather a nasty object to look at. We have a portrait of Cetewayo before us now, taken under the sanction, if not by the direct authority, of the Government representatives, in a dress which would be considered very far from the proper style for presentation at an English Court. But we should scarcely regard the dictum of the Lord Mayor sufficient to warrant us in pronouncing it as indecent. The Lord Mayor would scarcely like, he said, to make profit out of such things as these photographers did! We strongly object to anything like speaking evil of dignitaries, or we should be tempted to say that his Lordship's remark recalls that of another person who had a good opinion of himself, and was thankful that he was not as some others were. By a side wind his Lordship's remarks seemed to aim at the Stereoscopic Company, and he expressed his resolve to "get at" the publishers. Subsequently a letter from the solicitor of the Stereoscopic Company has appeared in the *Times*, denying that the Zulu photographs they published could be legitimately styled indecent, and expressing their readiness to accept service of process, which could bring them to the bar of justice to defend their position.

This is well. Photography has had enough to answer for; but surely its literal truthfulness of rendering ethnological studies is not to be pronounced indecent when the engraved studies of the same subjects pass scatheless. The Lord Mayor ridiculed the idea of there being any comparison between the drawings in the illustrated papers of the same and similar subjects and the photographs. In other words, he ridiculed the idea of there being any comparison between the truth of photography and the skill of the draughtsman. In matters of this kind the civic dignitary should remember decency or indecency generally depends on the intent; and he should also remember that decency or indecency is often in the eye of the beholder. The prurient mind will see indecency in a marble Venus. If his Lordship's zeal on behalf of decency were directed against the ugly nudities which placard the streets of

London, advertising quack medicines, it would be fully engaged, and the walls and hoardings might be relieved of a serious eyesore—nasty, if not obscene.

The case was eventually adjourned, and a few days afterwards the summons was dismissed. The Lord Mayor, who, on the latter occasion, contrived to bring upon himself a storm of hisses, incontinently closed the Court on Mr. Alderman Nottage rising to make some explanations in answer to the Lord Mayor's inuendoes in regard to his action in the matter. The worthy Alderman eventually, amidst loud cheers, impeached the Lord Mayor as having brought discredit on his office and on the ancient chair he occupied, the Lord Mayor in the meantime invoking the police.

COPYRIGHT IN PHOTOGRAPHIC PORTRAITS.

THE question of copyright in photographic portraits has been extensively discussed during the last week in Court and in the columns of the daily and weekly press. One might naturally have looked for some decisive, or at least, authoritative, dictum on the subject. No satisfactory conclusion or opinion—none, certainly, which can be pronounced as final—has been uttered. We certainly cannot accept the opinion of Mr. Justice Hawkins that the only way to stop the publication in future is for the person photographed to purchase the negative itself. Nor can we accept the dictum of counsel so learned in the law as Mr. Watkin Williams, to the effect that the copyright of a portrait is by the existing statute "vested absolutely in the artist." We have often stated that the Act is very clumsily worded; fresh sentences being grafted on a clause apparently nullifying preceding sentences. But the whole of the first section must be very carefully read before an opinion can be formed of its meaning. We will quote the section in its entirety before proceeding further:—

"The author, being a British subject, or resident within the dominions of the crown, of every original painting, drawing, and photograph, which shall be or shall have been made either in the British dominions or elsewhere, and which shall not have been sold or disposed of before the commencement of this Act, and his assigns, shall have the sole and exclusive right of copying, engraving, reproducing, and multiplying such painting or drawing, and the design thereof, or such photograph, and the negative thereof, by any means and of any size, for the term of the natural life of such author, and seven years after his death; provided that when any painting or drawing, or the negative of any photograph, shall for the first time after the passing of this Act be sold or disposed of, shall be made and executed for or on behalf of any other person for a good or a valuable consideration, the person so selling or disposing of, or making or executing the same, shall not retain the copyright thereof, unless it be expressly reserved to him by agreement in writing, signed at or before the time of such sale or disposition, by the vendee or assignee of such painting or drawing, or of such negative of a photograph, or by the person for or on whose behalf the same shall be made or executed; but the copyright shall belong to the vendee or assignee of such painting or drawing, or of such negative of photograph, or to the person for or on whose behalf the same shall have made or executed; nor shall the vendee or assignee thereof be entitled to any such copyright unless, at or before the time of such sale or disposition, an agreement in writing, signed by the person so selling or disposing of the same, or by his agent duly authorized, shall have been made to that effect."

It will be seen that the section sets out by vesting the copyright in a painting or photograph in the author or producer. Then comes a proviso to the effect that in case the picture be a commission (as a photographic portrait usually is) then the copyright shall belong to the person ordering or commissioning the work, unless it be by special agreement reserved to the artist. Then comes another provision stating that the vendee—that is, the person commissioning or ordering the work—shall not be entitled to the copyright, unless by a special written agreement with the artist. It follows that without a written agreement between the artist and the person ordering the portrait no copyright is acquired by any one—no copyright, in fact, accrues at all. A most lame and impotent conclusion to such a prolix section, which, we apprehend, can never have been

intended by the legislature, but is probably a result of much tinkering in committee. The issue is that portraits may be copied by unscrupulous photographers, and issued broadcast, without a remedy of any kind, that we can see, being applicable, not even Mr. Justice Hawkins' plan of buying the negative as a preventive.

Mr. Watkin Williams stated in Court, and reaffirms in a letter in the *Times*, that the copyright remains with the portraitist who persists, in defiance of remonstrance, in issuing for sale portraits of beautiful sitters. The *Times* endorses Mr. Williams' opinion, and an attempt is made to establish a distinction between the copyright in the negative and that in the print. With all due deference, we hold that the copyright is in the picture or design, which exists in negative and print alike, and in common.

There are conditions under which, however, the photographer acquires a copyright in portraits and a legal right to vend them for his own profit, independent of the wish of the sitter, and these conditions, we apprehend, prevail in the majority of cases where popular beauties have been sold in every variety of pose and costume. If the photographer produce a photograph of his own choice and intention, the sitter posing before the camera at the request of the photographer, then the copyright vests in the author who produces the work for his own purposes, and is secured in the possession all its advantages by the terms of the Act.

It appears that no one has a copyright in his own face. There is no copyright at common law. Copyright, it is alleged, is entirely a creation of statute law. We apprehend, however, that the cases are very rare in which a photographer would persist in selling the portrait of a sitter against the wish or protest of such sitter. The connection and reputation of a respectable photographer are his most valuable trade possessions; and it would be ruin to anyone to acquire the reputation of exhibiting or selling portraits of his customers against their express wish. The *Times* intimates that there is nothing to prevent an artist obtaining portraits of well-known men or famous beauties, and selling them. In photography, however, it is quite certain no such portrait can be obtained without the consent of the original. And although photography has come in for not a little rating for making popular the charms of those irreverently styled the "beauty women" of the season, it must be borne in mind it could only be done by their assent and assistance. Nay, it must be remembered, that this thing was first initiated at the Royal Academy Exhibition, where the duplicated portraits of one of the ladies, since much photographed, became the cyuourse of all eyes as a popular beauty.

The attention now called to the defects of the clumsy, obscure, and inefficient Act of 1862 will, it is hoped, enable the improved Bill of Lord John Manners to pass into law without much opposition or delay, as its provisions meet expressly many of the difficulties which have led to discussion in the cases which have recently occupied public attention.

On another page we print some extracts from articles which have appeared in various contemporaries, showing the uncertain state of public knowledge on the subject.

PRESS OPINIONS ON PHOTOGRAPHIC COPYRIGHT.

THE following extracts from various journals on the question of copyright raised by the recent libel cases.

Mr. Watkin Williams writes to the *Times* as follows:—

SIR,—The Royal Commissioners upon Copyright, in setting forth in their report (1878) the existing law in relation to paintings, drawings, and photographs, have been guilty of a serious inaccuracy, which, unless I am mistaken, has been the source and origin of much prevailing misconception as to the respective rights of the artist and his customer in the case of a

photographic portrait made in the usual and ordinary course of business. The language of the report (section 102) is as follows:—"The author of every original painting, drawing, and photograph has the sole right of copying, engraving, and reproducing it, unless it be sold or made for a good or valuable consideration, in which case the artist cannot retain the copyright unless it be expressly reserved to him by agreement in writing." This ignores the statutory distinction between the negative of the photograph and the photograph itself, and places the latter, so far as copyright is concerned, upon the same footing as paintings and drawings, and leads the reader to suppose that, as the law stands, when the photograph is executed for another for a valuable consideration, the artist fails to acquire the copyright unless it is expressly reserved to him. This is certainly a mistake. Take an ordinary example: You go to a photographer to have your photograph taken. You are informed upon enquiry that the charge is two guineas, for which twenty cartes-de-visite will be supplied. You enter the studio. Several negatives are taken; one proves successful. In course of time the twenty cartes are sent, and the money paid. The question now arises, has the artist in such a case the right, without your leave and against your will, to multiply and sell copies of your photograph? To this I answer unhesitatingly that he has such right; and if the language of the statute upon which alone the question turns is carefully looked at and considered in relation to the pre-existing law, the contrary will be seen to be utterly unarguable. The matter stands thus: By the common law no one has a copyright in the picture of himself; and, further, no author of a painting, drawing, or photograph had a copyright in his work. In order to remedy this latter defect, and in the interest of artists, the statute (25 and 26 Vic., cap. 68) enacted that "the author of every original painting, drawing, or photograph, shall have the sole and exclusive right of copying and multiplying such painting, or such photograph and the negative thereof." Thus was conferred upon the artist *prima facie*, and as the general rule, the exclusive copyright in every original photograph made by him, and also in the negative thereof, which is thus pointedly distinguished from the photograph. But then comes an exception, introduced by way of proviso, as follows:—"Provided that when any painting, or drawing, or the negative of any photograph, shall be made or executed for or on behalf of any other person for a good or valuable consideration, the person so making or executing the same shall not retain the copyright thereof unless it be expressly reserved to him," &c.; but in such case "the copyright of such negative shall belong to the person for whom it shall have been made." The result is that the copyright in every original photograph is vested absolutely by the statute in the artist, except in those cases where the negative of the photograph, as distinguished from the photograph, has been made for another person for a valuable consideration. The issue in each case, therefore, is brought back to this simple question of fact—whether, when the original photograph was ordered and the price agreed upon, the bargain really extended to and included the negative of the photograph, or merely the photograph itself. The price and the particular circumstances of each case may determine this question of fact either way; but for all practical purposes it may be safely said that the customer orders the photographs only, and does not pay for the negative. It follows, therefore, that a person having his photograph taken in the usual way and upon the ordinary terms, is powerless to prevent the multiplication and sale of his portrait by the photographer. It is scarcely necessary to add that this difficulty applies only to past photographs ordered unwarily, without foreseeing the danger. Once forewarned, the remedy for future photographs is simple, being merely a question of price. Lord John Manners' Bill to consolidate and amend the law of copyright, brought in but not proceeded with last Session, proposed to declare and amend the law upon this branch of the subject as follows:—Clause 34.—"The copyright in a photograph shall belong to the proprietor of the negative from which the photograph is printed. Where the photograph has been made on the order of any person for a valuable consideration, the proprietor of the copyright shall not be entitled to sell, expose for sale, or exhibit any copy of the photograph without the consent of that person, and that person shall have the same right of preventing the selling, exposing for sale, or exhibition of any copy of the photograph, and, if the copyright is infringed, of taking proceedings in respect of the infringement, as if he were the proprietor of the copyright.—Your obedient servant,

WATKIN WILLIAMS.

The *Times* says:—

This prosecution has terminated the career of a vulgar slanderer. We trust that it will have the effect of putting an end at no distant date to an anomaly which has come to light in the course of the proceedings. Astonishment is sometimes expressed that respectable ladies suffer their photographs to be exhibited in shop-windows in very dubious company. Inferences altogether too harsh are drawn from this common enough sight. The fact seems to be that the sufferers are sometimes powerless to prevent this unenviable notoriety. Mr. Watkin Williams told the Court on Saturday that Mr. West was desirous to stop the publication of photographs of his wife, and that he was advised that, in the present state of the law, this was impossible. Strange as the assertion is, it appears to be well-founded. Before 1862 no copyright in pictures or photographs existed. Any one could copy a picture or photograph and dispose of it at pleasure. The abuse was so flagrant that Parliament altered the law. But the Act which rectified this anomaly was indifferently drawn. Lord Westbury told the promoters of the measure that, if they wanted their Bill to pass, they should not strive to make it comprehensive and complete, and that they should be content if the Act remedied a few blots. "Make it imperfect," he said, and the promoters of it took him at his word. They made the meaning of the statute so imperfect that some of the clauses, and in particular that which governs copyright in photographs, are very difficult to construe. The Queen's Bench Division some time ago criticised unfavourably the language of the section relating to photographs; and, in his digest of the law of copyright prepared for the Copyright Commissioners, Sir James Stephen expresses his inability to be certain respecting the precise scope of the words of the Act. According to the letter from Mr. Watkin Williams which we publish to-day, the photographer has *prima facie*, and as a general rule, the sole and exclusive right to copyright in a photograph and negative. This, however, is subject to an exception. If the bargain with the photographer is that he is to be paid not only for the actual photographs, but for the negative also, the copyright of the negative will belong to the customer. This, however, is rarely done in practice. A person who goes to a photographer's shop does not think of the negative; he merely orders so many photographs; and if he does so he is powerless, in Mr. Watkin Williams's view, to prevent the sale of his portraits. If this be the state of the law, it is by no means the expression of perfect good sense; and, to make the matter worse, it is not quite certain that the enactment is so clear as Mr. Watkin Williams assumes. The fact is that in 1862, when legislators first busied themselves with photography, they did not distinctly foresee the uses to which it would be put. They did not anticipate that it might be made an instrument of social torture, a not unworthy substitute for the pillory; and even now, when everybody is alive to the existence of the nuisance, its abatement is found to be not at all easy. No one has a copyright in his face. If an artist manages to catch the features and expression of a handsome lady, and commits them to canvas without her leave, she cannot complain. No one can prevent anybody from drawing or painting his house. Even an architect cannot hinder a rival from sketching a building in the construction of which he has exhibited skill and ingenuity. It is impossible to make any laws by which artists will be prevented from sketching celebrated men or well-known beauties and selling their portraits. This is part of the price of fame, and must be paid with due resignation of spirit. But portraits, whether photographs or paintings, which are not taken without leave, stand on a different footing. The customers of a photographer go to him for their own pleasure, not for his profit; they order portraits for the gratification of themselves and their friends; and if the photographer takes advantage of an order given him to strike off a number of copies and to sell them for this own profit, he commits a moral fraud. He has obtained an unfair advantage, and if the law permits him to use it, the sitter has good reason to complain. Even before any copyright in paintings or photographs existed, Courts of Equity interfered to frustrate frauds not unlike those which are now perpetrated without any punishment. If a person happened to get pictures by unfair or surreptitious means into his possession, and took copies which he intended to sell, Equity Judges said that such a practice was improper and must be prohibited. They would not allow—to recall a famous case—publishers to vend etchings surreptitiously copied from the Queen's private collection. They have more

than once said that they would not permit copies of pictures which have never been exhibited or offered for sale to be taken and sold without the leave and against the wish of the artist or owner. They might well have shown as much consideration for the lady who goes to a photographer's studio to have a dozen cartes-de-visite taken for herself and her family, and who finds, to her horror, a month hence, copies of them stuck up in very varied company in a printseller's window. But the law, both judgemade and statutory, is defective, and it needs amendment. Had the Bill brought in last Session by Lord John Manners to consolidate and amend the law upon the subject been fortunate enough to pass, the evil would have been corrected, for it proposed to give any person whose photograph is taken a right to prevent the sale or exhibition of copies of it. Nothing less will satisfy the public mind now that it is impressed by the defenceless state of all persons whose faces are interesting. For the present, however, celebrities must be content to suffer from the enterprise of photographers, or to take care before they consent to sit in front of a camera that all rights in the negative and photograph are clearly conveyed to them. Such is the strange state of the law that at present every one who is famous would do well to call in his attorney before he has his portrait taken.

The *Observer* says:—

Most of us have, at some time or other, been photographed; have posed before the lens; have gone through the customary ordeal; have had a couple of copies sent for our inspection; and have ultimately been furnished with a dozen or couple of dozen, or, as the case may be, four dozen copies of our features. Photographers, as a rule, are respectable men, whose business it is to conciliate their customers, and it is very seldom that a photographer, even in a country town, will endeavour to attract custom by exhibiting, as a specimen of his art, the portrait of a local celebrity, without having first obtained express consent. If the Dean of Barchester sits for his portrait to the local photographic artist, it is not only understood to be part of the bargain that the photograph shall not be public property, but were the understanding broken the photographer would lose his customers, and would be practically ruined. Of late years, however, a certain unwholesome love of publicity has grown up, and photographs of persons generally known in the world have been sold whole sale. Into the general aspect of the question which has thus been raised it is needless to enter. There are certain persons whose features are, in a certain sense, public property. It is only reasonable that photographs of the Queen, and of various members of the Royal Family, of Her Majesty's Ministers, of Bishops, of members of the Houses of Peers and Commons, of celebrated preachers, authors, poets, actors, actresses, and artists, should be sold by the hundred. It can hardly be called a morbid curiosity that tempts us to fill the conventional photograph album with representations of the Queen, the Prince and Princess of Wales, Mr. Ruskin, Mr. Millais, Mr. Irving, the Earl of Beaconsfield, Mr. Gladstone, Mr. Tennyson, Madame Patti, Miss Ellen Terry, and Mr. Spurgeon. But there are persons who may have notoriety thrust upon them without having sought it. And as we are all photographed upon an average once a year it is important to know how far we can control the issue of our portrait for sale. If a lady has had her photograph taken solely for herself and her friends, and if circumstances have given her a transitory notoriety, has the photographer a right to sell her portrait indiscriminately? It is strange that this point of law should never have been raised, and that we should not yet have had upon it the decision of a competent tribunal. Such, however, happens to be the case, and it is easy to see how the difficulty arises. We go into a photographer's shop, and order a hundred copies of a photograph of our own features, or of those of our wife. The photographer in due course send the parcel home, we distribute the copies among our friends, and we hear no more of the matter until we find our photograph on sale at almost every small shop in England. Some few years ago Bishop Colenso, of all people in the world, woke one morning to find himself famous. His book on the Pentateuch had come out, and there was a demand for his photograph. The demand was at once met by the reproduction by the hundred of photographs already known to Dr. Colenso's friends, and the negatives of which had been taken with a view to private circulation only. But at present, unless very incorrect statements have been given to the world, there must be ladies and gentlemen by the hundred whose photograph is being sold, and a large profit being realized upon its sale, not only without their consent, but positively against their express wish. No man who respects himself cares to have notoriety

thrust upon him; still less does he care to find his wife the heroine of club gossip, and to find her portrait being sold wholesale, with the customary "reduction on taking a quantity." What is a man to do under such circumstances? Is he in a position to institute legal proceedings against those who have thus vexed and annoyed him; or has he no resource except to protest against the liberty which has been taken with himself and his family? The photographer will argue that his contract is only to supply a certain number of portraits. This he has done. He has taken the photograph, the dozen, or two dozen, or twelve dozen copies have been sent in, and beyond this he will contend we have no manner of property in the negative. It was executed for us at our own request, but it is not, on that account, our own; and, in so far as any public curiosity may attach to it, the right of sale and reproduction belongs, it will be urged, to the photographer himself, by whose labour and time, and with whose materials it was originally taken. There are, of course, two aspects to this question. In the first place, we have to ask ourselves whether a man has any copyright in his own features; and, secondly, whether he has any right to prevent the sale of copies from a negative which has been taken for him at his own request.

As to the first of these questions there can be no doubt whatever. The features of any member of the public are public property. No man can declare that he is essentially a private person. He may be unwilling to have notoriety put upon him, but he cannot help it. If the public interests itself in him, he becomes *ipso facto* a public man, whether he desires it or not. And a public man has no copyright in his own features. Any engraver or publisher who chooses may make and issue a portrait of Lord Beaconsfield, or of Mr. Gladstone, or of the Prince of Wales, or of Major Chard, or of Lord Chelmsford, or of Dr. Talmage. Nor would an injunction stop the sale of such portraits. It would be difficult in such a case for the plaintiff to show that he had been in any way damaged, and, indeed, the point is so clear that the question it involves has never been raised, and may be taken as practically settled by common consent. The only case in which a man can interfere with the publication of an engraving or picture representing his features, is where the portrait so produced amounts to a libel. If it be a fair representation of him, then, however much he may object to its sale, he is practically without redress. Photography, however, has for some years past been specially legislated for by statute, and there is an Act of Parliament—25 and 26 Vic., c. 68—by which it is specially provided that, "when any painting or drawing, or the negative of any photograph shall be made or executed for or on behalf of any other person for a good or valuable consideration, the person so making or executing the same shall not retain the copyright thereof, unless it be expressly reserved to him by agreement in writing, signed by the person for or on whose behalf the same shall be made or executed." But on the other hand, the copyright does not even vest in the person for whom the photograph has been made, unless there has been at the time an agreement in writing between him or her and the photographer to that effect. And accordingly, if we are to accept the authority of Dr. Shortt, the latest writer on the law of copyright, the copyright in a photograph is altogether gone "unless (1) it be expressly reserved to the photographer by agreement in writing, or (2) be reserved by a similar agreement to the person for whom it has been taken. If, in other words, Mr. Jones has his photograph taken for him by Messrs. Brown, the right to reproduce copies from the negative belongs neither to Mr. Jones nor to Messrs. Brown, unless there has been some positive agreement at the time embodied in writing. Photographers have always avoided such an agreement, and contended that by the custom of the trade the negative is their own, and the custom has practically been always recognized. We are not aware that they have ever yet definitely claimed to possess the right of reproducing copies and selling them. As has been said, the question has never yet been raised; but there can be little doubt as to how it ought to be decided. A man has no right whatever to prevent a portrait of himself being sold unless he can in some way claim property in the portrait itself or in its original, and his claim to a particular photograph will be found, if we consider the matter, to rest in the fact that the original negative was taken for him with his own consent. Let us, for instance, suppose him to be a public man, who, on some particular occasion, delivers an address to a large audience. During the course of the address, and without his consenting to the fact, or even knowing it, his photograph is taken by a photographer. Clearly, under such circumstances, he himself would have no right to the photograph. We can easily test the matter

by asking what would happen if an injunction to stop the sale of such a photograph were issued. But it is another matter where the original negative has been specially taken by the consent of the person whom it represents. Common sense would suggest that the copyright in such a case should belong to the person for whom the photograph was taken; and as there was some doubt whether this were the law or not, the Government last session introduced a Bill to settle the matter, which, however, did not pass further than its first reading. According to this measure, the copyright is to belong to the proprietor of the negative from which a photograph is printed. But where the photograph has been made on any one's order for valuable consideration, the proprietor of the copyright will not be entitled to sell a copy without that person's consent, or to expose it for sale, or exhibit it. And the person who orders the photograph is to have the same right of preventing the sale, the exposing for sale, or the exhibition of any copy, as if he were the owner of the copyright. Similarly, he is to be empowered to take proceedings in case the copyright be infringed. With regard to the duration of the copyright, which is at present for the lifetime of the artist, and seven years afterwards, the proposal is to fix it at thirty years from the date of publication. Were this measure to become law there would be at once an end to the legal difficulties which now exist. For at present, evidently, a doubt can be raised as to the copyright in a negative of a photographic portrait. The moral aspect of the case is clear. If a lady goes to a photographer, and pays him a handsome sum—and photographers' charges are seldom moderate—to take her photograph, and to provide her with a hundred copies of it, by all reason and justice not only the copies themselves, but the negative from which they are taken, and the right of reproducing copies from that negative, belong, or ought to belong, to her. Copyright, however, is no part of the common law. It is purely the creation of statute, and the issues we have suggested have never yet been contemplated by statute law, and so remain altogether unlegislated for. In short, the question of a man's copyright in photographs of himself is a *casus omissus*, and will so remain until legislated for. Even should the Bill which Lord John Manners last Session introduced become law, it will still remain an open question whether a man can forbid his photograph being sold, provided it has been taken without his permission, and he has not paid for it. If, for instance, he is, as we have already suggested, photographed while delivering a public lecture or address, it will still be open to argue that his features are as much public property as are a landscape or a well-known view, and that, in reproducing them, and multiplying copies of them by the camera, a photographer does him no harm. His copyright will, in a word, be limited to those cases where the original negative has been executed for him at his own request, and he has paid for its execution.

The *Weekly Despatch* says:—

It is the privilege of Mr. Cornwall West to be the husband of Mrs. Cornwallis West, and in that capacity he appears to have suffered a grievous wrong at the hands of some photographer or photographers unknown to us. And, according to the merciless processes of logical deduction, had it not been for the offending photographer or photographers in question the man Rosenberg could not have been put under his trial to answer to one of the counts in the indictment preferred against him. Seeing so many portraits of Mrs. Cornwallis West exposed in the shop-windows, this thoughtless fellow jumped to the conclusion that the pictures were exhibited and sold with the sanction of the fair original and her husband; and, adding to lack of business caution a too high opinion of the powers of satire possessed by his literary staff, he published comments which doubtless in his and their opinions partook of the nature of humour. Only they who have made the attempt and succeeded know how difficult it is to be funny; and judging from internal evidence, Rosenberg's scribe was not possessed of that experience. Hence he overstepped the narrow line which divides sarcasm from scurrility, with what result to his employer we know; for Mr. Justice Hawkins does not, as far as we can see, intend to take a particularly lenient view of the case. That the portraits of Mrs. Cornwallis West—some of them in doubtful taste—were exposed for sale contrary to the expressed wish of that lady's husband there cannot be a question of doubt, for the gentleman himself has sworn it in evidence. Surely, then, there should be some law to reach the offending publisher, assuming the publisher to have offended. So far as we understand the law of copyright bearing on such a case,

which was not made quite clear yesterday, in spite of the vigorous protestations of Mr. Watkin Williams, it seems that when a money payment is made to a person for producing a portrait the copyright rests with the purchaser; but where no such consideration has passed, the right to reproduce the original is vested in the artist or handicraftsman, the maker of the likeness. From the explicit assurance of Mr. Cornwallis West we gather that his wife's negatives have been in every instance ordered in the regular way of business, and paid for. Indeed, anyone who assumed the contrary would not only be guilty of an impertinence, but would infer that Mr. Cornwallis West had no legal ground of complaint against the publisher of his wife's portrait. The timely interference of this outraged gentleman throws an entirely new light upon the much-discussed question of the propriety of offering for sale the photographic likenesses of ladies of rank—otherwise undistinguished. And but for this episode how could the common people have known that the simpering presentments of the Duchess of This and the Countess of That and Mrs. So-and-So were retailed at a shilling apiece in defiance of the protests of the noble and gentle ladies and their legal lords? If Mr. West's case is not exceptional, the sting is at once taken out of the sneer of the cheap satirist when he rails against the fashionable world for permitting the likenesses of rich and modest ladies to occupy the position of matter in the wrong place in the album of the typical 'Arry. It has been said that 'Arry, an ignorant and coarse sensualist, gloats upon the forms of the fashionable beauties of the day. And this is a reflection horrible to contemplate. There are, however, numerous classical stories of youths having fallen desperately and passionately in love with the vivid creations of the great Athenian sculptors, and possibly what happened in ancient Greece may have been repeated in modern England. Of course, the argument that because a callow snob may fall in love with a lady's likeness, therefore ladies shall not have likenesses taken, is of itself absurd. But if we go further and find that the unnecessary and uncalled-for cheapening of these commodities encourages such unpleasant familiarity, an appearance of reason is given to a contention which otherwise would be unsupportable. The man Rosenberg, who was found guilty yesterday afternoon, has already suffered imprisonment, and will probably suffer more, for incautiously enlarging the bounds of an example set him by more respectable journalists. And therefore it is to be regretted that Mr. Cornwallis West and the rest of the noblemen and gentlemen who may be sufferers in their feelings through the illegal obstinacy of publishers continuing to issue likenesses of ladies after having been warned to desist, did not long ago write to the newspapers explaining the true facts of the situation. It may be urged that the newspapers would not have been compelled to print their explanations, but for our own part, we are inclined to the opinion that every courtesy would have been accorded by the Press to citizens so grievously wronged in a delicate private matter. It is almost a pity that we have no law making it imperative on newspaper editors to insert a correction of any misstatement concerning an individual, even where such misstatement has not been damaging; although the more this question of ladies' likenesses is considered, the more apparent becomes the damage inflicted upon innocent members of the upper classes. We have frequently seen allusion made to the anomaly of exhibiting the portrait of some fair and chaste votary of fashion cheek by jowl with those of women whose sole title to kinship with our mother Eve in Paradise before the fall is the fact that they are shown naked and not asbamed. But how unreasonable is such an objection. The more or less lovely female members of the aristocracy are not responsible for the bad taste of a shopkeeper to whom a proper sense of the fitness of things has been denied. As well might the admirers of Lord Beaconsfield complain that his photograph was hung up alongside that of Dr. Lynn. It does not follow because one is a professed juggler that the other is a juggler also. In the old days of the Keepsakes, Annuals, and Books of Beauty, what purported to be portraits of noble and gentle ladies were published from time to time without unfavourable comment from the Press. Such portraits, however, were seldom sufficiently like the originals to induce personal allusions, and, moreover, they were published at prices which put them out of the reach of the 'Arrys of the period. Unfortunately the likenesses of the reigning so-called beauties of the day, although improved as far as possible by retouching upon the negative, retain too much of the form of the originals not to make the comments which they call forth exceedingly painful

to the friends of the sitter; particularly as, from the evidence of the shop windows, it would seem that some ladies set up for beauty on a slender capital, and thus encourage that sneering attitude of mind which is one of the greatest drawbacks of an irreverent age. On every ground, therefore, let us hope that we have seen the last of the Photographic Beauty Craze, for the negative quality of prettiness is an insufficient claim to publicity.

Mr. Bassano writes a letter to the *Times* which throws some light on the alleged difficulty of checking the publication of photographic portraits of private persons.

Sir,—By your remarks on the publication of Mrs. Cornwallis West's and Mrs. Langtry's photographs, the whole body of photographers is placed in a most unenviable and, indeed, invidious position, and, unless some defence is offered, the members will be looked upon as an unscrupulous class of the community, whose greed is superior to their sense of honour, and whose only consideration is to put money in their pockets—honestly, if they can; if not, otherwise. Mr. Watkin Williams, Q. C., stated at the trial that "Mr. Cornwallis West took every step in his power to prevent the photographs of Mrs. West being published." I appeal to your sense of justice to allow me, as a photographer who has had the pleasure of taking negatives both of Mrs. Cornwallis West and Mrs. Langtry, to say that Mr. Cornwallis West did not appeal to me, at least, in vain. Immediately upon his personally expressing his disapproval of the publication of Mrs. Cornwallis West's photographs (permission for which had been granted), I withdrew every copy of the portrait from circulation, and countermanded several orders then in course of execution. I was not even aware, until I saw Mr. Watkin Williams's letter in this morning's issue of the *Times*, of the power which the law gives to photographers with respect to negatives they may have taken, my sense of what was due to a client who unsuspectingly placed himself in my hands being sufficient to protect him from any unfair use being made of that which he had a moral, if not a legal, right to have the entire control over—namely, the issue of copies from the negative which he had intrusted me to produce. A very important omission appears to me to occur in Clause 34 of the Copyright Bill introduced by Lord John Manners last session. It is therein stated that no copies of a photograph shall be sold (or published) without the consent of the "person" whose photograph has been taken. The word "person" is not sufficiently accurate, because in the case of a married woman a dispute might arise if she had given consent to the photographer for the publication of her portrait without, or in opposition to, the wishes of her husband. Therefore it should be definitely stated in such a case that it should be necessary to procure the husband's authority before proceeding to publication.—Your obedient servant, ALEXANDER BASSANO.

25, Old Bond Street, October 28th.

GERMAN CORRESPONDENCE.

BY DR. VOGEL.

PHOTOGRAPHIC BLOCK PRINTING IN JAPAN—RESTORING THE BATH—CARVALHO'S PAINT FOR STUDIOS.

It has often been tried to obtain printing blocks with the help of heliography, and with much good success; but while an easy way to produce a printing-block with the same rapidity and precision as a silver picture has not yet been found, it looks very much as if the far East would present us with such a process.

Baron Stillfried, now professor of photography in Japan, and superintendent of the photographic department of printing, reports that a Japanese possesses the secret to make printing-blocks with the help of photography, by using a sensitive substance, long known to the varnishers in Japan. This substance is red-brown, soft, like putty, and has the property to harden in the light, and to become insoluble in certain solutions. With the doughy substance a wooden block is coated, smoothed with rollers, and the whole is lighted under a negative. The lighting lasts in the sunshine a whole day, and the lighted parts become thereby hard like stone, and dull, the rest remaining soft. It is now easy to remove the soft parts with a wooden knife. The hard parts resist the knife, and the whole is then worked with an instrument resembling a comb, or the

soft part is removed with a solution. The remaining relief can be hardened in the light and used at once for printing. More than this Stillfried could not ascertain. The Japanese have always been very reticent in regard to the fabrication of their excellent varnishes, and it therefore might not be easy to obtain any further information about this sensitive varnish.

In your last number I found, under "Gihon's Gatherings," some very valuable items; among others, one entitled "How to Sun a Bath." I believe the recipe to be good, especially for America, where there is no lack of sunshine; but, nevertheless, the process requires several hours of preparation in summer. The bath has to be neutralized first, then acidified again after sunning, &c.

Much easier the same result is obtained without the sun, by using permanganate of potassium, which was first recommended by Crookes. For twelve years I have used this substance, and do not need to sun a bath. A few minutes only are necessary for the purpose, and I never had a failure, and long ago I recommended this way of restoring a bath instead of sunning, but it seems as if not all photographers were successful with it. Usually the mistake is committed of using entirely too much permanganate, thus neutralizing its beneficial effects. I take one part permanganate, 1 part nitric acid, dissolve in 100 parts water, and of this solution I put one drop into the silver bath which is to be restored. If the bath now contains organic substances, the beautiful rose colour which the first drop produced will vanish quickly again. Then another drop is put in, always shaking, and if the rose colour vanishes again inside of a minute, another is added, and so on until the point is reached when the rose colour will remain permanent while shaking, when no more permanganate must be added. In this way a bath may be restored in five to ten minutes with permanganate. If no organic substances are in the bath, the first drop already will impart to it a rose colour, which will last several minutes. I had baths, with which I had to use 20 to 30 drops of solution of permanganate, and others which were restored already with 3 drops. But too much of permanganate is always injurious, and very apt to produce insensitiveness or fog. Of course, only organic matter is removed from the bath by permanganate, but not so all other defects (for example, excess of iodide of silver). I know people who imagine they can remedy all and every defect with permanganate of potash, but it cannot be done.

Since the new patent law has come into existence in Germany, a great many photographic patents have appeared. In a year forty to fifty photographic novelties have been patented, but real value only a few of them possess. Some of these patents are already extinct again, as they realized so little to the patentees that they were not inclined to pay the patent tax for another year, though the same amounts only to about \$12. The undeniable worthlessness of many patents has had the result that everything patented is viewed with suspicion. Formerly, when only really new and practical inventions were patented, the case was different. I see that recently some American inventions were patented here, and I do not believe that they will amount to more than the other patents. Lately a patent has been applied for for Carvalho's orange-pea-green paint for studios. I have read the application, and must own that I have seldom seen so much nonsense condensed in a few pages as in this report. It is undoubtedly obvious that the shadows of our models, if they shall be effective for photographic purposes, have to be lightened by photographically effective lights. Such a light is the white or blue, and therefore the reflecting walls of our studios must be painted blue, white being too glaring for the eyes. If anybody asserts having obtained better results in a studio with orange-pea-green walls than in one painted blue, he simply deceives himself, and such a delusion happens not unfrequently with photographers. Only a short time ago a photographer brought me some "lightning" collodion of which he seemed to think wondrous, but which I found,

upon testing it in my studio, much less sensitive than my own collodion.

If a photographer, as I read in some English paper, experiments to-day in a blue studio, and the day after tomorrow in one painted pea-green, and thinks he can perceive that in the latter case the picture is much better, I do not place any weight whatever upon the fact, because no man, not even the very best photographer, can judge what change the chemical strength of light has undergone in three days. The better result may be traced to any other influence, but not to the pea-green coat of paint; and anybody who will prepare two reflecting screens of equal size, painting the one light blue with ultramarine, and the other pea-green, and place first one and then the other on the shadow side of a person, taking one right after the other, in equal light, can judge for himself how much the pea-green colour is worth.

Talk in the Studio.

CETEWAYO.—We have been favoured by Messrs. Marion and Co. with copies of the portraits of the dethroned Zulu chief, taken by Messrs. Crewes and Van Lawn on board the steam ship *Natal*, at Cape Town, as recently described in our pages, and also portraits of a group of his wives. These are, we believe, the only genuine portraits of Cetewayo, and the only ones likely to be issued, as he does not intend to sit again. Possibly, since the Lord Mayor's homily on the grossness and impropriety of Zulu fashions and sartorial customs, Messrs. Marion may hesitate to issue these portraits, as it is a serious thing to shock the taste of a potentate with fine and imprisonment within his power.

PORTRAITURE ON GELATINE PLATES.—Our readers are familiar with the name of Mr. A. Wellesley Turner as one of the earliest and most intelligent workers with carbon. We have recently been favoured by him with some charming specimens of card and cabinet portraiture, which illustrate a fact we have often had occasion to note, namely, that the most skilled and intelligent workers are generally abreast with every stride of progress in the art. The examples of portraiture sent by Mr. Turner are from gelatine plates, and are in every way fine examples of high-class work: delicate, yet vigorous, finely modelled, without any approach to coarseness. Several of the portraits are of children, illustrating the rapidity of the work. It is very gratifying to us to find that the work of one whose communications have so often been of service to our readers places him beyond question in the highest rank of portraitists. Mr. Turner has been good enough to promise details of his gelatine experiences to the readers of our forthcoming YEAR-BOOK.

A PHOTOGRAPHIC ACTION FOR BREACH OF CONTRACT.—At the Clerkenwell County Court of Middlesex, before Mr. Judge Whitebread, the case of *Henderson v. Kurtz* was heard, in which the plaintiff, a photographer of Glasgow, sued the defendant in the same profession, carrying on business in Canonbury, to recover the sum of £20 for alleged breach of contract under the following circumstances. It appears from the plaintiff's statement that in consequence of an advertisement in *May* last he entered into negotiation for the purchase of defendant's business, which, with good will, stock, and the remainder of a lease, was to be sold for £150, and that in consequence of the defendant's representations he came from Glasgow to see the business, and paid the defendant £20 as a deposit; the balance was to be paid on the completion and transfer of the lease. The plaintiff said that from subsequent enquiries he had made, he found the value of the business grossly exaggerated, and that instead of three and a half years, there was only about one and a half years unexpired term to run. The plaintiff here put in copies of letters he had written to the defendant for the return of his money, failing to obtain which he brought the present action. The defendant being called, said he never told the plaintiff there was any three and a half years to run, and that his business was well worth what it was represented to be. In reply to the learned Judge, defendant said he had no evidence to call as to the value of his business, upon which the learned Judge said it was evident that the case had been misrepresented to the plaintiff, and therefore he should order the defendant to return the deposit of £20 he had received, as well as pay the plaintiff's travelling expenses from Glasgow and back. This judgment was accordingly entered in favour of the plaintiff.

AT MARYLEBONE, Alfred Paul de Witt, 32, photographer, of

103, St. John's Wood Terrace, St. John's Wood, was brought up on a warrant before Mr. Mansfield by Chief Inspector Shore, of Scotland Yard, for unlawfully and wickedly selling certain obscene printed photographs to St. Leger Lonsada, an officer of the Criminal Investigation Department. Mr. Collette prosecuted for the Society for the Suppression of Vice; Mr. S. B. Abrahams defended. Mr. Collette said that the prisoner was a photographer, and besides carrying on a legitimate business, it was known that he photographed bad characters from all parts of London. He also produced photographic pictures from negatives sent to him for the purpose. This case originated under a warrant taken out under Lord Campbell's Act, and a warrant was also obtained to arrest the prisoner. St. Leger Lonsada said that he received information from Chief Inspector Shore, and also from Mr. Collette, and then went to 103, St. John's Wood Terrace, on the 13th inst. He there saw the prisoner and told him that he wished to have his photograph taken. After having sat for his portrait, he asked the prisoner if he had any other photographs, and he answered that he had a few negatives, but he seldom kept them, and generally destroyed them after he had taken them. The witness remarked that he should like to see them, and the prisoner showed him the negative produced. The witness ordered some copies from those and other negatives which the prisoner showed him. He also purchased a photograph, and then left, the prisoner telling him that the others would be ready shortly. On the following Monday the prisoner handed him the six photographs produced. The witness had paid him £1 9s. 6d. for them and his own photograph on the previous Tuesday. The witness took the pictures to Scotland Yard and showed them to Chief Superintendent Williamson, and by his instructions he called on Mr. Collette the next morning. The witness was present that morning at the prisoner's house with Chief Inspector Shore, when the negatives produced were seized. They corresponded with the pictures he had bought. He recognized among another parcel of negatives now handed to him, and which was seized that morning, two negatives that the prisoner had shown him. Cross-examined, the witness said that the prisoner told him the negatives did not belong to him. He pointed out in a book the name and address of the person to whom the negatives belonged. He also gave up certain negatives. There was no attempt at concealment. Chief Inspector John Shore said that in the morning he went with the last witness and another officer to the prisoner's house and told him that he was an officer of police and held a warrant for his arrest. The prisoner produced six photographs and four negatives, all of which were obscene. The witness pointed out that the negatives did not represent the photographs, and the prisoner then sent his man upstairs for some others from the studio, and eight more were handed to the witness of an obscene character. The prisoner said that he had taken the eight negatives for a gentleman, and the six copies were made for him also. Four negatives, he said, he had taken as works of art, and should after a time destroy them. He did not think there was any harm in keeping them. He was told the harm was in selling them. He was asked if he had anything to show that what he had said about the negatives was correct. He showed the witness an entry of £2 15s. 6d. in a book with reference to them, and also another entry with respect to photographs from them. There was a name on the book, but the Court did not think it was necessary for the witness to make it public. Mr. Collette observed that this person might be indicted with the prisoner in this matter. Mr. Abrahams said that the prisoner would reserve his defence, and he was then committed for trial, the magistrate consenting to take two sureties in the sum of £10 each for his appearance at the Sessions. A summons was applied for under Section 2 of Lord Campbell's Act to show cause why the photographs should not be destroyed, and it was at once granted.

To Correspondents.

♦♦♦ The pressure upon our columns this week arising from the large amount of matter on the subject of photographic copyright—all of interest to photographers—compels us to leave over much matter in type, amongst which we may mention a notice of portraiture at the Photographic Exhibition, the continuation of "Looking Back," Press Opinions on the Exhibition, Dr. Monckhoven's Lecture on Gelatino-Bromide of Silver, and some other matter.

H. RICHARDSON.—The transparent compound used for making pictures of this kind transparent is white wax. Sometimes castor oil is used, sometimes paraffin, sometimes Canada balsam; but in the case in question probably white wax, or one of the encaustic pastes for which we have often given recipes.

THE PHOTOGRAPHIC EXHIBITION.—Several correspondents ask us how long the exhibition will remain open. We have repeatedly announced that it will remain open until the 13th of November. It is open daily from 10 till dusk, and on Monday and Saturday evenings from 7 till 10 o'clock.

BUMBLE BEE.—The quantity of ferridecyanide is one drachm, just the same amount, in the same proportion of water as the persulphate of uranium. The solutions are mixed in equal proportion when required for use, and after filtering add the few drops of gold solution. A dipping bath is the best mode of using. The formula has appeared in several YEAR-BOOKS.

A STRUGGLING PHOTOGRAPHER.—We do not know whether the gentleman in question will contribute the promised details in next YEAR-BOOK. We do not at present, indeed, know his whereabouts. We shall endeavour, however, to give the requisite information.

H. COX.—We have not yet received the information promised, but hope to do so shortly. Your letter contained no stamp or stamped and addressed envelope.

AN ENGLISH RETOUCHER.—We cannot give you advice or aid as to obtaining an engagement as retoucher in France. The only plan will be to advertise in the French journals, or to make special application to French photographic establishments. We should think the most likely journal would be the *Moniteur de la Photographie*, address, 3, Rue Talma, Passy, Paris.

COLOURIST.—The plan of colouring photographs at the back, both in oil and water-colours, has frequently been patented, but we do not think any valid patent is now in existence which will interfere with you if you wish to practise the method. It is simplest and most effective in oil. One effective method consists in colouring a vigorous impression somewhat strongly, and then superposing accurately upon it a light delicate impression which has been made transparent. But there are many modifications of the idea which ingenuity will suggest.

YOUNG CHEMIST.—Various metallic salts are more or less sensitive to light. You will find Hunt's Researches on Light valuable in your investigations. The salts of copper and zinc, of which you say you have an indefinite recollection as being described as sensitive, are probably the following. If a concentrated solution of sulphate of copper (blue vitriol) be mixed with a concentrated solution of bichloride of zinc, a white precipitate of perchloride of copper is formed, which blackens when exposed to light. This quality is only present whilst the precipitate is moist, and disappears on drying, as does also the blackness previously assumed.

J. T. B.—The money granted by the Government for the encouragement of original research is, we believe, always placed under the control of the Royal Society, and is generally set apart by that Society for the purposes of special research definitely indicated and placed under the charge of special investigators appointed to the work. Such money rarely or never finds its way into the hands of private investigators, however valuable their labours or needful the assistance. The only chance would be to communicate with the Royal Society through its officers, all courteous gentlemen. They are Professor Stokes and Professor Huxley, honorary secretaries, and Mr. Walter White, general secretary. Address them at Burlington House, where the Society's rooms are.

DRY PLATE MAN.—We believe that the decision of the committee to whom the matter was entrusted will be made known early in the session now coming on, possibly at the first meeting. The subject has been under active investigation. Time, to test keeping qualities, was necessary before a decision could be made. Some of the competing plates were sent out, we believe, on a voyage to the Tropics and back to test them satisfactorily. Your question as to whether anything has oozed out as to probable issue is scarcely a fair one. If it had, it would be wrong to repeat it publicly.

COPYING OLD PORTRAITS.—A correspondent whose letter is mislaid, requires information about the possibility of obtaining a good copy of an old and somewhat imperfect portrait. We have seen amazingly fine copies of old, imperfect, and faded photographs produced by various photographers. The memorial portraits of which our correspondent speaks as having seen near Trafalgar Square are by Mr. Piercy, a very capable artist, who has made a speciality of this kind of work, which he accomplishes with very great success, supplementing the appliances of photography by skill as an artist with the pencil. The address is, we believe, No. 12, Pall Mall East; it is next door to Trafalgar Square. Mr. F. Piercy is the artist's name.

Several correspondents in our next.

The Photographic News, November 7, 1879

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY IN THE NAVY—GULLS AND SWALLOWS—THE SWEDISH EXPEDITION.

Photography in the Navy.—It is a strange thing that, while our Army makes such good use of photography, and prescribes a course of instruction in photography to staff officers and officers in the Royal Engineers, the Navy takes little or no interest in the art. In the Royal Naval College at Greenwich, if the camera does make its appearance occasionally, it is scarcely in an official manner, and it is only because officers in the navy are sometimes amateurs that we get pictures and photographic records of the places they visit. It is usually the surgeon or assistant-surgeon on board that practises with the camera, he in all probability being the only man who has a convenient place to serve as a laboratory. But the combatant officers count many competent photographers. His Royal Highness the Duke of Edinburgh, it may be remembered, is—or, at any rate, was—a practised photographer, for recently he seems to have devoted his leisure more to the production of soft music than soft sounds. The name of Captain Turton, R.N., is also familiar to our readers as an officer of the navy who is an accomplished photographer; while in the case of the last Polar Expedition, under Captain Narcs, we have several examples of naval photographers, the results of whose labours are among the few objects that remain to us as *souvenirs* of that voyage. In an interesting account that recently appeared in the papers of a visit to Pitcairn Island by Her Majesty's ship *Opal*, we find that a series of views of the settlement and its inhabitants was taken by one of the officers of the *Opal* who was an amateur photographer, and happened to have his camera with him. From the fact that much interest has been aroused in connection with this Island, and that it is not visited sometimes for a twelvemonth together, it is very likely that the photographs thus secured will be of considerable value, and doubtless in all quarters, official and otherwise, they will be eagerly looked for. Under these circumstances it is a pity that photography is not officially recognized in the navy; there must be so many instances in which, if ships were provided with photographic apparatus, their officers could render valuable service at the various stations and places they visit. Reports that are sent home by naval officers relating to coast or harbour works, or the possibility of making the same, or respecting surveys that have been made, would all be enhanced by means of photographs, and doubtless a practical naval officer who is also a photographer could suggest countless other applications to which the camera might be put with advantage. We supply most of our big armoured ships with an officer learned in chemistry and electricity for torpedo work, and he would be specially competent to supervise photographic duties and photographic supplies. As it is, there is no one officially entrusted with a camera throughout the navy, and if it were not for the amateurs among the officers, who appreciate the value of the camera to such an extent that rather than be without the means of photographing they purchase one out of their own pocket, we should never get a glimpse of the beauties of Pitcairn Island, and of other distant lands, to say nothing of photographic records and pictures of technical work. When the Arctic Expedition was ordered to be provided with photographic apparatus, and to carry one or two officers versed in photography, it was found that none of those selected for service in the *Alert* and *Discovery* knew how to coat or develop a plate. The consequence was that they were put through a course of hurried teaching, and instead of being able to rely upon their own judgment in selecting their outfit, were compelled to call in advisers to help them. Providentially, the War Office was able to come to the assistance of the Admiralty in this matter, and placed the services of two of their offi-

cers, Captain Abney, R.E., F.R.S., of Chatham, and Mr. Baden Pritchard, F.C.S., of the War Department Photographic Establishment at Woolwich, who were able to give the necessary aid. But the time has now come for the Admiralty to consider whether they should not take steps to include a camera and its requisites among the stores of a sea-going ship; and from the fact that we have now rapid and trustworthy dry plates, the uses to be made of photography are even more numerous than formerly. It is true that dry plates, as a rule, will not stand a sea voyage without special protection, but this would, no doubt, be devised, if our naval officers had the opportunity of trying.

Gulls and Swallows.—We wish photographers would try to reproduce some other birds on the wing besides the gull and the swallow. It is not the birds so much as their names that we object to. Mr. Robinson, we verily believe, only showed his photographs of gulls for the purpose of worrying critics, and, so far as we are personally concerned, we don't like being worried. Supposing you have, at one time or other, expressed a belief in the bona fide character of such pictures, it is not pleasant to be continually reminded of your dictum. On after occasions, when you are holding forth on the merits of this picture or that for half an hour, getting, perhaps, rather hot in your arguments, it is not nice for a bystander to take you up coolly with, "How about Mr. Robinson's gull?" As humble critics, we protest against being taken in. And, now, as if your capacity for gulping down *canards* were unlimited, people ask with a wink, how about Mr. Gale's swallow? We object to be gulled, or being asked about our capacity to swallow. We are no more liable to be taken in than other people. When Mr. Robinson's picture was under discussion, there appeared several letters written in these columns, written by that gentleman, on the subject of "Sea gulls and others," and we suppose now that we shall be treated with communications anent the swallow and its victims. Why, therefore, we ask again, should the gull and the swallow be picked out by photographers, unless, indeed, they are meant to be symbolical, and put forward with the sole intention of worrying critics?

The Swedish Expedition.—It is interesting to learn that the Swedish expedition, which was recently successful in making the voyage by the Arctic Ocean along the northern shores of Europe and Asia, was provided with a camera, and brings back with it some valuable photographs. These were taken with a view to illustrate the report, which is shortly to be issued, of the voyage, one of the most remarkable in modern times, and will tend to support, we are told, the opinion of those who took part in the expedition, that the route is a practicable one for steamers. The English edition of the work is to be published, we believe, by Messrs. Sampson Low and Co., and will, no doubt, command general attention.

"LOOKING BACK."

BY AN OPERATOR.

CHAPTER IX.

I BECAME THE OWNER OF A NICE QUIET BUSINESS.

I DO not know if you will find this paper so edifying as some of the foregone, but I flatter myself you will find it more useful in its aim: it is especially addressed to young men who may have an ardent wish to rush into business, and become their own masters. Before I start I may say that I mean to tell a plain, unvarnished tale—to speak the whole truth, &c., and otherwise hold myself up to all such ambitious young men as an example, but to no one as a pattern. It was not inclination, so much as circumstances that led me into business on my own account. I had been happy—perfectly happy—in my roving, *ignis fatuus* sort of life! I had no regrets—no cares—and troubled myself little about the future. I could always make more than I spent, and, in fact, very often discovered myself to be in better circumstances than those I served. I had certainly

met with eccentric characters—men with low and groveling ideas—men with wild and Quixotic notions—men with noble aspirations—men with extravagant ideas, and men with none—good men and bad—honest men and prigs! Yes; it would be almost an impossibility for a man who has travelled so many years not to have met with despicable employers—mean, pitiful, little wretches.

"Shadows, my lord, beneath the soldier's notice!" And as such I shall pass them over, merely saying that with the exception of this latter class, I managed to rub along on fair terms with them all. With this I have reason to be thankful, for I believe there are some employers, respectable as the world goes, who seem to forget entirely that the servitor is of the same flesh or blood, or that those who

"Are born with fortune's yoke about their necks,
And *that* is galling in itself enough!"

I will slip over a few years, and briefly inform you that I have become a staid, sober, and devoted Benedict. A few years slipped over in peace and quietness, when death entered our little home. The place, the house, became distasteful to us, and, to make a long story short, I gave up my situation in one of the best houses in the north of England, and removed to London.

It was the end of autumn. I was a month in London before I began to be disheartened. But I had then tried everywhere and everything—I had left no stone unturned; my advertisement appeared regularly in the photographic papers; I had called at the wholesale houses, and left my name and address; I had gone up one side of Baker Street and down the other with a pocketful of certificates and a bundle of specimens, but all to no purpose. It was a frost—a biting frost—and I was locked out in it. Now it was not a case of distress with us, as you shall find, but only an eager wish that we might be settled once more, and get out of the dingy lodgings—we were in a quiet street off the Goswell Road—and have once more a home of our own, that kept us awake half the night. That wish was the ruin of us! It was a very natural and simple wish to bring us into trouble, was it not? Now I shall tell you how it happened.

One bright sunny day, I found myself wandering and brooding—not a thousand miles from the "Angel" at Pentonville, nor even a hundred from the "Cock" at Highbury—when suddenly I found myself before a little house occupied by a photographer: the show cases were trim and clean, and the specimens good. It was just such a place as one would suppose where a quiet decent living might be made. The situation was capital (so one might have thought) either for a connection or chance. "Ah!" thought I, "what a happy beggar must the owner of this spot be, with a nice little wife and a nice little business; and a bit of garden behind where he can actually sit beneath his own vine and fig tree on a Sunday evening and puff his mild Havanah! Heavens! it is Elysium!"

With such thoughts I wound myself up a narrow staircase, and stood in a room decently furnished and hung round with specimens. Not seeing anyone, I coughed. It had the desired effect, for instantly a tall, thin man issued from a cupboard at the other end of the room. This cupboard was the dark-room. He was evidently a dirty operator, to judge by his long hands, for they were streaked all over with pyro and silver; something had tickled his nose in the dark room, and in scratching it he had given it a smut as well. Fancy the effect of such an apparition upon a nervous child or a fastidious lady! After courtesies had passed between us, during which he smiled all over, evidently thinking he had got a sitter, I dispelled the illusion by asking how he found business, and hoped he had use for an assistant.

"I wish to the saints I had!" he ejaculated fervently. Then, seeing a droll look on my face, he qualified his exclamation by adding, "for your sake."

The ice being broken now we went at it tooth and nail.

I had to tell where all I had been, and he had to show me over the shop, and let me see the enormous collection of negatives his predecessor had made. "He made quite a fortune, my predecessor did, and went off to 'Merricker to spend un. As for myself, I finds as 'ow the purfession don't agree with me, so I'm determined to sell hout."

"What! Sell it! Ain't it paying, then?"

"Paying, I should think as it his!" indignantly retorted Mr. Jinks, "I tell yer it's me health demands a change. Pay! it pays me well enough, and if any young feller as knew the business and pushed it, you know, and had a wife as would assist him in the shop, it's a regular little sit down, I kin tell ye! Ye'll excuse me, I know," he continued, looking at his watch, "but it's one o'clock! No, don't go away! Hi'm a man of regular 'abits, hand it is the hour when I has my forenoon snack! 'Ere, boy," he called, "jest get me a nice rump steak from over the way, potatoes hot, and some vegetables! And hi, boy! don't forget the stout and a penn'orth o' puddin'."

Now, there was nothing extravagant in this order, but the tone in which it was given did more to impress me with the fact that there was a snug little business doing than all his former talk, and I departed more than ever impressed with the belief that the owner was a particularly lucky beggar.

There was a long talk and a calculating of the needful that night in a second pair back, Charles Street, Goswell Road, the result of which was a second visit paid to that enviable little business. Jinks evidently knew he had got a nibbler. "Well, dear sir," he cries, "I do not much care for leaving it until the spring: but for a consideration and to oblige, I don't mind."

I will not trouble you with all the details connected with the buying of that little business: suffice it if I say the landlord was visited; an agreement made out and properly attested at Somerset House; a deposit left at the gas office; forty pounds paid to Jinks—twenty for the business and twenty for the furniture and show cases, that being all that I cared to buy, as I had apparatus of my own. "I'm so glad of that, ole man," cried Jinks, when he heard the latter proposal. "I shouldn't liked to have parted with my camera under fifteen quid, and I rather fancy it will prove useful when I goes abroad." Jinks, being a single man, did not stay in the place, so the two attics that we proposed to make our dwelling rooms were unfurnished, and accordingly another five or six pounds went to make them comfortable. Then came three days of hurry and bustle, cleaning out the place, and preparing the dark room, for I found the stock of chemicals there almost *nil*, and then, with little over two pounds in my pocket, I settled down to watch for customers. The excitement was over now, and, like the man who married in haste, I got time to repent at leisure. I had everything in going order by Wednesday morning, and on Saturday night I found that I had had only two sitters—two servant girls—one 5s. and the other 2s. 6d. That looked like a quiet business, did it not? "Never mind," quoth my wife, "it has not been very nice weather, and we'll likely do better next week." Next day being Sunday, I resolved to have a rest to enjoy my pipe, my newspaper, and my book; it never entered my head that such a nice little business in so quiet a locality, could be guilty of the enormity of Sunday work; but I was soon undeceived. About twelve o'clock there came such a knocking at the door that my wife thought the house was a-fire; but when I opened the door, there was Jinks wild with excitement. "My dear sir," he cried in agony, "what on earth is the meaning of this? Do you want to spoil the little business?"

I told him I had no such intention.

"Then why the devil have you not out the show cases?"

"Sunday!"

"Sunday be blowed!" was his irreverent answer. "You will sometimes do more on a Sunday here than you will all the week, so out with them, my boy!"

So out they went, and sure, as he said, before dinner time I had taken over a pound. But, great heavens! was this the nice quiet business—was this the Arcadian joys that I had promised myself on the Sundays? Away, delusive dreams! my eyes are open, and I gaze on sad realities. Six days in the week shalt thou labour, and on the seventh do all thy work. Such was the jocular way Jinks put it. There are some jokes that I can never see the point or fun of them, and that is one. We were both very much depressed that Sunday evening, and, a word in your ear: I do not think our religious principles were so much hurt as that we felt a sort of social falling off—a sinking in the scale—a lowness that seemed to equalize us with the touters of Pentonville and Euston Road. I need not tell the reader that during the course of the first week I discovered that to make a living in the place I had to put my shoulder to the wheel. I might have exclaimed, in the words of the noble Baron Bilkarsky, "Hit's no use tawkin'; summat must be done."

Portrait clubs were beginning to be common then, and I conceived a notion that I could manage a pretty fair thing out of them. I advertised in the *Chronicle* for agents—energetic agents. For three days my door was crowded by all the imbecile loafers in Clerkenwell and Islington. You may think I exaggerate, but, by my halidome, it was perfectly amazing the crowds of ragged lazaroni that applied for that situation of mine. The landlord of the publichouse at the corner offered to make it worth my while to keep on inserting it—he was evidently experiencing the saying of an ill wind blowing no one good.

I got four clubs started. The best one was conducted by a young man in the Aldersgate Post Office. A drawback that these clubs had were that *they* all wanted to be taken on a Sunday. Jinks was not wrong: it proved my busiest day. So things looked a little better for a bit. But one black, gloomy day my police rate was handed in to me, and as I counted the money I had I discovered that we were eating up all that we were making—that, in short, if we could sit without taxes or rent we would be making a bare living. This was disheartening. "Summat" else must be done.

I hit upon another idea that at first promised to tide me over all my little and accumulating difficulties. I went round the different schools, and solicited the honour of photographing the scholars in groups. I met with wonderful success, and we passed our Christmas with hopeful hearts. But it was only a lull in the storm that was bound to swamp our little craft. Had I had a friend, or had I had another fifty pounds in the bank when I took that business, I have not the slightest hesitation in saying that I *would* have made it pay. But it was the want of ballast that upset us when the gale came.

I shall give you the sequel of the nice quiet business in Chapter X.

[The Editor will be obliged to "An Operator" if he will forward promised information regarding retouching varnish, as there are several applicants waiting for it.]

(To be continued.)

THE PRESS AND THE EXHIBITION.

[From THE GRAPHIC.]

This exhibition is rapidly developing into one of the most interesting London "Annuals," not only owing to the numerous fresh processes by which photographs are yearly made more perfect, but to the pains which photographers themselves are taking to elevate their art, and transform the stiff, hard-set face of the ordinary portrait into a thoroughly artistic, unaffected, albeit correct, likeness. That they have succeeded we are far from saying, but we may point to the various portraits by A. Boucher, to those of Lady Gilford by Lombardi, to some admirable studies from life, such as the "Little Flower Girl," by W. Gillard, to the charming portraits of children by W. J. Byrne and W. E. Debenham, to the autotype prints of the young Princesses of Wales by Robert Faulkner, and to several very fine specimens from H. S. Mendelssohn, and from

the inimitable "Mora" of New York, as some of the best examples of their kind that we have seen. Nor should we omit the enlarged portraits of Wilkie Collins and Charles Reade by the Woodhury Company and A. Lombardi respectively. The various instantaneous processes afford great facilities for taking sea views, and two little gems taken on instantaneous gelatine plates by Joseph Gale, "Brixham Trawlers," are particularly noticeable. Other seascapes are some really magnificent studies of the "Dogs of Scilly and their Prey," by Colonel Stuart Wortley. Mr. Vernon Heath is to the fore with his large landscape photographs, those of "Burnham Beeches" being particularly good. His "Stoke Pogis Church," enlarged by the Autotype Company, is the largest in the room. Some very good views of Tiutern Abbey are shown by the School of Military Engineering, of North Devon scenery by William Bedford, of Scotland by James Valentine and Sons, of Ireland by Payne Jennings, while foreign scenery is best represented by a very good view of the Villa Clara Bavono by E. Hyol. In animal subjects T. J. Dixon undeniably carries off the palm with his fresh and bold "Studies of Lion and Lioness," while in floral subjects Mrs. S. G. Payne exhibits some particularly pleasing photographs, as also a very well arranged group of "Fish and Moorhens." There are numerous attempts at photograph-pictures, amongst which we may especially particularise a most realistic "Fern Seller," by H. Garrett Cocking, an exceedingly pretty interior, "Between the Lights," by H. P. Robinson, and a "Child Artist"—an exceedingly ugly little girl, by the way—by the Autotype Company, from a negative by A. Sachs. Space will not allow us to do more than mention the various portraits taken by the luxograph and the electric light processes, the photographs on porcelain by the Autotype Company, which strike us as capable of still further improvement, the various subjects printed in platinotype by W. Willis, Jun., the highly interesting photographs of the Dutch (Willem Barents) Arctic Expedition of 1878, and the curious unique photograph of the mirage seen over the steeple of Tenby Church last May, when the launch of a gun-boat at Pembroke Dockyard, some twelve miles distant, was clearly portrayed in the sky. Altogether, the exhibition is well worth a visit, but we would draw the attention of some of the exhibitors to the utter incongruity of their frames. Surely a heavy gilt surrounding does not harmonize with a simple little landscape.

[From TRUTH.]

PHOTOGRAPHY, to my thinking, has become a perfect nuisance, and I was going to say the same thing of photographers; for, in the way of artistic prigs, perhaps there is none so to be shunned as these gents. of the camera, who look upon all mankind, and nature into the bargain, with such a glassy eye to business. More sensitive than their own plates in their artistic feelings, they are desperately anxious to be thought artists in the fullest sense; and I see that the Council of the Photographic Society have assumed all the little airs and graces of the Royal Academy. They advertise themselves with Her Majesty the Queen and H.R.H. the Prince of Wales as patrons, and they drop the word "photograph" entirely; everything is a picture. But let any painter or man of taste look in at the Society's exhibition, and see whether that is the way to portray nature. The art of worthy old Madame Tussaud is quite as good and twice as natural, and in the Baker Street Gallery you are not obliged to go into the chamber of horrors. I don't mean to say that photography is not a useful and an amusing thing in its proper place—in copying maps, engravings, drawings, and giving exact likenesses of people and places; but, when it is attempted to assume for it the merits of art, photographers make themselves ridiculous. Unfortunately, most people, and many professed artists, not knowing what art is, are captivated by the photograph, and so the thing has proved much more of a curse than a blessing so far as art is concerned. It has done more than anything to debase popular taste, to destroy the modern school of painting, and to wipe out the poetic all over the world.

[From PUBLIC OPINION.]

THE improvement in photographic processes is well marked this year. The process known as the "gelatine" is, in our estimation, as yet unequalled, and this Exhibition by a young and certainly rising Society brings out great improvements. The scenery and trees exhibited by Mr. Payne Jennings are exceedingly good, and finely worked. Faulkner exhibits some wonderful specimens of the different expressions in the same children, analogous to

those which Rejlander showed during his lifetime. The gems of the Exhibition are the small frames, Nos. 244, 245, and 246, views taken on gelatine plates, developed four weeks after exposure, printed by Willis's platinum process by Dr. William Huggins. This new process gives an entirely new effect to the picture, and anything finer and more beautiful has never been shown in photography. Mr. Debenham's pictures (105 and 127) of portraits of children are worthy of notice. Messrs. W. Cobb and Son send some very good studies, printed in platinum, for gelatine negatives (338 and 339), and there are very few "amateurish" pictures exhibited. The Photographic Society seems to have gone in now for steady practical work, and to have entirely passed what has been called the "orthomorphic" stage of its existence. We are always pleased when a science is fighting its way to the front like that of photography, though we are in a difficulty when we try to subordinate its proper position in Comte's classification. And on the true answers to the questions, "Is photography an exact and a mathematical science?" and "Are its objects exact or concrete?" will depend its future position in the scale of applied sciences. The present Exhibition by the Photographic Society will tend much to the recognition by outsiders of the precise and exact character of the science, and the Exhibition is a most pleasing and instructive one.

[From the QUEEN.]

WHILST mechanical invention as a substitute for manual labour and mental activity may be regarded with considerable jealousy, there can be no question that the progress of such invention is making rapid strides. It is, however, quite possible that the substitution of the threshing machine for the flail, the grass-cutting machine for the scythe, and a hundred similar ingenious discoveries, may be the means of opening the question of a great and important social problem, hard to answer satisfactorily. In noting the development of the art of photography, whilst we hear of taking photographs upon gelatine direct, of photographing in colour, and of similar remarkable discoveries, yet no one, we should imagine, with any artistic knowledge, would say that the finest possible photographic portrait is at all equal to a first-rate miniature—the latter, unfortunately, an art now almost entirely superseded by the former. Certainly not the least interesting portion of last winter's exhibition of the Royal Academy was the collection of lovely miniatures, exhibiting as they did qualities necessitating high mental powers in their production, as well as great technical skill. In the present exhibition of the Photographic Society in Pall Mall East, the visitor will find that, whilst there is much to interest, there is but little illustration of those higher art qualities to which we have referred. The collection, nevertheless, is the best we remember to have seen, and, speaking generally, there is evident advance in the value of the landscapes, in the smaller portraits, and in the animal studies; but the enlarged life-sized heads are, as hitherto, a failure. Glancing very briefly at a few of the works illustrative of the different classes of subjects, Mr. Vernon Heath's "Buruham Beaches," and "Stoke Pogis Church" (Nos. 7 and 8) are fine in tone; while the "School of Military Engineering, always strong in the periodical exhibitions here, has some singularly fine examples in views of Tintern Abbey and Chepstow Castle, (Nos. 18 and 19). Mrs. G. S. Payne shows us little artistic feeling in Nos. 22 and 29, "Designs for Easter;" and in No. 112, an enlargement by the Autotype Company from a negative by Vernon Heath, of "Stoke Pogis Church," we have one of the few perfectly successful examples of very large photographs in the Gallery. Probably this romantically-picturesque old church was never seen to better advantage—

Beneath those rugged clms, that yew tree's shade,
Where heaves the turf in many a mould'ring heap,
Each in his narrow cell for ever laid,
The rude forefathers of the haulet sleep.

Having almost the effect of beautiful drawings in red chalk, are Robert Faulkner's autotype prints of the Princesses Maud, Victoria, and Louise of Wales will be sure to delight the spectator; and No. 114, "Dorothy Fletcher" and "Edward di Otrante," are equally excellent. Passing on, the visitor should note A. Boucher's half-a-dozen portraits direct from life (No. 137); and in Nos. 197 to 204 Colonel Stuart Wortley's valuable studies of clouds and sky effects. "The Fern Seller" (gelatine plate), by H. Garret Cocking, is a well-studied figure of a woman with a child in her arms and basket of ferns at her back, whilst the wall against which she stands is placarded with playbills and advertisements of various entertainments. Another worthy figure picture is by W. Gillard, "The Little Washerwoman," a

small profile whole-length of a child with bare feet, standing at a wash tub. Among the animal studies we noticed an untouched carbon enlargement (No. 111), "Lion and Lionesses," by T. J. Dixon. Here, indeed, we see the lion in the natural terrible grandeur of the kingly brute. Another fine picture of animals (No. 161), an elephant, zebra, and two others, is by F. York; whilst a third, scarcely so important, is No. 324, "Horses, &c.," by S. G. Payne. Upon the screens are a series of most interesting works in "Inhabitants of Armenia" and "Incidents of the War, 1877-78," taken by Nikitin, Tiflis, exhibited by Leon Warnerke, and a number of views in India, by A. T. W. Penn. On the table, among many interesting and valuable examples of the art, are two gelatine negatives (Nos. 421 and 422) by Alexander Cowan and Samuel Fry.

[From the PRINTING TIMES AND LITHOGRAPHER.]

THE exhibition shows a marked advance in productions of artistic merit. In addition to the improvement which is always inseparable from an increased acquaintance with the beautiful as exhibited in the works of our painters and sculptors, we think something may be due to the use of the rapid gelatine processes that have, during the past twelvemonth, been forced upon the attention of photographers. Portraits and landscapes can now be taken in about one-tenth of the time formerly required by the collodion process, the consequence of which is that expressions in portraiture and effects in landscape are easily caught now which formerly escaped during a comparatively long exposure. The professional photographer can now purchase ready-prepared plates of exquisite sensitiveness, so that his mind can be directed more to the art phase of his work than to the regulation and manipulation of chemicals, while in outdoor work, moving figures, animals, clouds, waves, and shipping, are photographed with a rapidity truly marvellous. The present exhibition will well repay a visit from all interested in the advance of photography.

[From the ILLUSTRATED LONDON NEWS.]

VARIOUS causes have been unfavourable to the exhibition of the Photographic Society. Most potent among these causes has been the extraordinary dullness of the sky for many months, in consequence of which some only of the leading contributors of former years have been able to prepare works for exhibition at the last moment. We are told that part of the planet Jupiter is obscured at this moment by a remarkable red spot; but the astronomers of Jupiter must have discovered that an equally singular spot, varying in hue from a dirty brown to a dull leaden colour, has hung over the earth for a long time past, hiding from view that portion of the pigmy planet where England is unfortunately situated. Another reason why some of the customary exhibitors are absent, or not in force, probably is that many photographers are not yet familiar with the more rapid gelatine process lately introduced. When you can justly object to a photographer that he has exposed his plate some seconds too much or too little, you may fairly expect him to do better next time; but when you tell him that his exposure has been too long or too short by a quarter of a second he may not unreasonably urge the difficulty of appreciating such fractional atoms of time. The value, however, of the increased celerity of these new methods for seizing a transient expression or gesture—for everything that has life or movement—can scarcely be over-estimated. But we had already seen what may be done by the "instantaneous process" properly so-called. And, again, Colonel Stuart Wortley astonishes the visitor, and affords delight to the marine painter, in his series of coast scenes in Scilly and elsewhere, wherein the passing clouds in splendid compositions of various aerial strata, the march and welter of twinkling waves, and breakers dashing themselves among rocks, and even the flying scud, are caught and fixed for ever. In other studies from the Scotch firths and coast (23), by Messrs. Valentine, there are effects of reflections on the sea which might scarcely be credited in a picture. A small photograph by A. Donald, called "The Trout's Retreat" (143), with an added sky, is also strikingly expressive of wind in the sway of the foliage and the drift of the luminous clouds. The value of the rapid process, by means of a small negative, enlarged in the printing, for rendering animals, is also well shown by T. J. Dixon, among others, in studies (at the head of the room), of a grand old lion and lioness—though the enlargements are obviously "touched up." The necessity, again, of a process, instantaneous or nearly so, for "taking" children, is no less obvious—for are they not restless little animals? Stimulated,

probably, by the success of Mr. Faulkner, several contributors have sent frames of photographs of children only - notably Messrs. W. E. Debenham (105 and 127), W. J. Bryne (90 and 91), and E. Greaves (237), in which frames some of the little darlings are quite sculptural in their beauty. The children by Mr. Debenham are especially charming in pose and grouping, and as photographs they are technically perfect. Yet Mr. Faulkner is scarcely rivalled on the larger scale of his vignette heads called "Studies of Expression" (114), and the children of the Prince of Wales (113), which, reproduced by the Autotype process, resemble drawings in red chalk. *Apropos* of the autotype the Company exhibit specimens of its excellent process, including some examples of the success lately attained in reproducing monochrome studies by artists or pictures through the medium of a monochrome drawing prepared by the artist himself—see, for instance, "Studies from Nature," by R. Elmore, R.A. (340). There seems, however, something left to desire in the rather rough and not pleasantly-toned enamel photographs by the Company at the end of the room—*i.e.*, photographs burnt-in on porcelain and earthenware. This application of photography may, nevertheless, prove acceptable for decorative purposes to manufacturers, if not to the more artistically-educated portion of the public. We need hardly say that the bulk of the exhibition consists of landscape work—prominent among it being the productions of Messrs. Bedford, Heath, the Woodbury Co., the Chatham School of Military Engineering, and others scarcely, if at all, inferior. The names of the contributors we have mentioned is sufficient guarantee of the high manipulative excellence of their exhibits, and it would be supererogatory to attempt to criticise this department in detail had we space to do so. The autotype enlargement of "Stoke Pogis Church" (112), from a negative by Vernon Heath, is a *tour de force* as regards size, if a little hard—perhaps inevitably so from the nature of the subject. By its side is an equally large magnificent piece of woodland scenery, "Pain's Hill, Cobham," enlarged by the admirable process of the Woodbury Company, from a negative by Captain G. H. Verney, which is remarkable for the breadth and true value of its gradations, combined with clearness. The School of Engineers at Chatham maintains its reputation in a series of beautiful views of "Tintern Abbey," &c. (14 to 20). The merit of these views appears more extraordinary when we consider that they are produced in the leisure of the Corps of Engineers, not by professionals. They reflect great credit on the teacher of the school, Lieutenant L. Darwin (son of the philosopher), the hon. sec. of this Society. Among other works in this class deserving particular notice are W. J. Grant's views taken during the Dutch Arctic Expedition, 1878, F. G. Norton's views in Demerara, and a series of scenes in Armenia, by Nikitin, a Russian photographer. We would also mention four or five tender little landscapes (245 to 247), by W. Huggins, taken on gelatine plates, developed four weeks after exposure, and printed by Willis' platinum process. To be able by this means to take a view and develop long after would evidently often be a great advantage in travel. Mr. W. Willis, jun., exhibits many samples of the process of printing we have just named (the platinotype), invented by him—a chemical novelty whereby some disadvantages of the process of gold, and still more of silver, printing are obviated. The objections to platinum printing at present are that the tone is cold, and the shadows a little opaque or smoky. Returning to the figure-works, there are, of course, many exhibitors of portraits and studies besides those already named. As noteworthy for some novelty of aim we may mention the frames of studies taken on dry plates (295), by H. L. Mendelssohn, which evince much artistic feeling in arrangement and lighting; the so-called "Panel Portraits" (292), by H. Rocher; "Portraits direct from Life" (137), and others by A. Lombardi; by the Woodbury Company, from negatives by Lock and Whitfield; a study of a reaper in sunlight (147), by G. Bruce; portraits by H. Vanderweyde, taken by electric light (which renders the photographer independent of the fickle sunlight in this climate), soft, yet effective, but a little theatrical in pose; and others taken by the Luxograph light. But the portraits are generally touched up with the pencil, or "retouched," using the word the photographer borrows from the artist—as though the previous work had been done by hand! The difference of many of the portraits consists merely in the degree in which this retouching is concealed. The object is not simply to remove blemishes in the photograph itself, but to give an artificial smoothness to the flesh gradations. And we cannot too often repeat that precisely in the degree that this falsifying, dishonest stippling is used (with a mistaken aim at flattery) so does the photograph lose its essential value and one great recommenda-

tion as a trustworthy record of scientific accuracy, so far as that is possible within its actinic, chemical, and optical limitations. It cannot be too strongly insisted upon that photography and art are two worlds which are absolutely and must eternally be distinct from each other in the very nature of things. For this reason we must still more strongly condemn what are called pictorial photographs, or "combination prints"—obtained by the piecing together of two or more negatives, taken necessarily under different and, therefore, incongruous lighting, with (generally) diverse degrees of exposure, and from various points of view. There are fewer examples of such artifices than usual here; but No. 232, "Between the Lights," by Mr. H. P. Robinson, will bear out our remarks. A little girl is seated by the fireside, and the object is to render the effect of firelight on her figure in opposition to the daylight that enters the window; but an artist will instantly feel that the true effect of firelight is not rendered, and that it has not a just relation to the light of similar intensity at the window. Moreover, the photograph is obviously retouched.

A PHOTOGRAPHIC ACTION.

At the Metropolitan County Court, Bloomsbury, on Friday last, the case of *McAndrews v. Furrer* was heard before Mr. Judge Bacon, in which the plaintiff, a photographer, sued the defendant, John Furrer, trading as the Cornhill Photographic Company, to recover the sum of £50 for an alleged breach of contract under the following circumstances. Mr. Fitzgerald appearing as counsel for the defendant, and Mr. Vernell, barrister, for the plaintiff. From Mr. Vernell's opening it appeared that the plaintiff had entered into an agreement with the defendant under the form of an irresponsible partnership for three years terminable at one at the option of either party; the defendant employing his client at a nominal salary of six pounds weekly, with a participation in the profits, to manage the business at 59 and 60, Cornhill. The plaintiff was a photographer of twenty years' experience. On the 19th of April of the present year the agreement was entered into, and as the concern was only in its infancy the plaintiff only received three guineas a week instead of the six, when, after he had been only six weeks in the defendant's employment, he was summarily dismissed on the 6th June on the ground that he was incapable of carrying on the business through habits of intoxication, and that when he applied to the defendant for the money due to him, and for the fulfilment of his contract, he was refused: hence the present action. The plaintiff being called, corroborated his counsel's opening, but in cross-examination admitted having brought spirits into the studio, but was never the worse for liquor, or asleep when on duty. He had a black eye on two occasions, but that was the result of accident. He was not intoxicated when he photographed the defendant's wife, although he had to take six negatives before he succeeded in doing so. In re-examination, he said that since he left the defendant he had had an excellent certificate from Mr. Zorloni, of Scarborough, that he was a good poser, a good chemist, and most attentive to sitters. This being the plaintiff's case, it was urged on the part of the defence that the plaintiff was incapable of managing the business on account of his continual drinking habits. John Furrer called, said he was defendant in the present action, and he dismissed the plaintiff on the 6th of June, as he always appeared sleepy and listless, and certain he was an established drinker and could not properly attend to sitters. Mr. Clement, in the defendant's employment, said he had seen the plaintiff intoxicated, and on two occasions with a black eye. The defendant's traveller gave corroborative evidence, who, in reply to the learned judge, said he had written to the defendant, informing him of the plaintiff's state. The evidence of the defendant's wife went to show that when she called at the studio the plaintiff was too shaky to take her portrait. After two other witnesses had been called in support of the defendant's case, the learned judge, in giving judgment, said that the agreement before him decidedly took the form of a partnership in which the plaintiff was to share the profits, which appeared to him to be *void*. The partnership had no right to be annulled except on good grounds, and he considered the plaintiff was not entitled to have this agreement cancelled. Still it was a question as to what amount of damage the plaintiff had sustained, and it appeared to him that as the plaintiff had received six weeks' pay from the defendant, who worked the business at a loss, he was only entitled to nominal damages. Judgment was accordingly entered for the plaintiff for one penny damages, with taxed costs on the higher scale.

THE INDICTMENT AGAINST PHOTOGRAPHERS.

IN the late action for libel it was not Mr. Adolphus Rosenberg alone who was on his trial: photography and photographers were also practically indicted, and if a certain portion of the press were the authoritative tribunal it would have gone hard with the alleged criminals. Oddly enough—or, perhaps, not odd, because it is common—it is in the journals which live by gossip, which trenches, as everybody knows, close on scandal, that the greatest virulence in imputation against photographers is found, justifying Tennyson's line that

"They that most impute a crime are pronest to it."

Vanity Fair charges that photographers seem to regard themselves as chartered libertines in multiplying copies of the portraits they have been employed to take. After making the statement, the writer fortunately proceeds to the illustration, or proof, which is ridiculously inconsequent. He narrates a case in which a photographer did not multiply copies, but, having taken a lady's portrait, he subsequently finished a copy on porcelain, not for publication or miscellaneous sale, but to submit to the lady for purchase if she liked it. As her husband did not care to make the purchase, he wished the photographer to efface the portrait, "which," as the narrator adds, "was done." What more would he have? The custom is, we believe, by no means uncommon amongst enterprising photographers, when they have obtained a fine negative which seems to especially lend itself to special style of finished picture, to produce a completed portrait in such style for the purpose of submitting to the sitter for purchase. In many cases the customer regards this as a compliment, and gladly purchases the portrait which is so satisfactory. The photographer referred to by *Vanity Fair*, it appears, found, as a rule, that his sitters thanked him for giving them the chance of seeing such portraits of themselves without incurring expense, and, in the majority of cases, purchased the picture. We have, it is true, heard such a mode of doing business condemned as undignified in the photographer; but we have never before heard the whisper of a suggestion that it was any injury to the sitter, who incurs neither trouble nor risk in the matter.

The fact that the photographer destroyed his work and effaced the portrait brings us to another point. However confused and illegal the ideas of the various commentators on the subject of copyright in photographs, they are, with few exceptions, at one as to the idea that photographers do publish the portraits of their sitters in defiance of their wishes. The public may be fairly held as justified in such an opinion. Mr. Cornwallis West stated by his counsel, and himself repeated on oath in the witness box, that he had been vainly endeavouring for twelve months to stop the issue of his wife's portraits. No one would like to be guilty of the rudeness of saying that this was untrue. But

everybody would, we think, be disposed to say that the statement wanted some explanation. We have repeatedly heard the remark, "Is it to be believed that the lady's portrait appears in constant variety of style and costume entirely in opposition to her wish?" And we have also heard it added, "Is it possible that the able portraitists who produce the charming portraits of these society beauties are so destitute not only of honourable feeling, but of common prudence, that they risk reputation and connection for the paltry profit on the sales, however extensive, of half-a-dozen individuals whose beauty and reputation for beauty must rapidly fade?"

We had the fortune recently to be present in an assembly which included some of the most able and distinguished portraitists in England, and this question came naturally upon the *tapis*. From one after another of the most distinguished portraitists came the indignant denial of the imputation. And from one after another came the expressed conviction of assurance that no portraitist known to them would issue or publish a portrait of a sitter in defiance of expressed wishes. Further, that none of them ever had, or would, issue prints of a sitter without the consent of that sitter in writing. Some of them had taken portraits of some of the society beauties, and been requested by the sitters to publish them; but none had ever parted with a print, or exhibited a print as a specimen, in opposition to the wishes of the subject of the portrait.

We believe that an honourable and honourably-conducted profession has been grossly misrepresented and calumniated. And we regret that no machinery exists whereby a federate and representative reply could be given, and protest made. No society, association, or combination of professional photographers exists, and no society in which trade interests can be considered or discussed. We have often suggested that the formation of a league or combination of photographers who might take united action when occasion occurred, would be beneficial to all professional photographers, and we repeat the suggestion now. The allegations so repeatedly made of late are calculated to leave an impression on the public mind to the effect that various dangers lurk in the photographer's studio, and that they are at the mercy of the photographer, who may sell copies of every portrait he takes if he can turn a penny by doing so. The world is, unfortunately, full of weakly and illogically timid people who will be deterred from entering the photographic studio under such an impression, thousands of whom might otherwise have been valuable customers. If an official round-robin, bearing the names of the most respectable portraitists, disabusing the public mind of such an impression, could have been published, the effect would have been most useful. It is not improbable that some portions at least of the press would have felt it just to publish such a document, and, at any rate, there would have been no difficulty in securing publicity by advertising.

COPYRIGHT IN PHOTOGRAPHS.

THE state of the law of copyright in photographs, and the probability that a new law will be passed next session, give especial force to our suggestion as to the importance of forming a league or guild of professional photographers, whose duty it would be to see that the interests of professional photographers are duly considered in the new Act. The painters have been well represented in committee, but, so far as we know, photography not at all; and the fact that, so far as we can see, photography has not been neglected, has been due to the right feeling of the committee rather than to the effort of any one representing the interests of photography. A letter from Mr. Bassano, in a recent issue of the *Times*, points out in the new Bill—abstract of which we recently published—what he conceives to be serious errors. Mr. Bassano is an eminent and skilful portraitist, and should be able to offer an

opinion of value on the subject. But we submit, with all respect, that his objections are not tenable, and the correction or alterations he suggests are not beneficial to photographers. First, the new Bill distinctly lays down the principle now generally held "that the copyright in a photograph shall belong to the proprietor of the negative." Mr. Bassano says that an experienced photographer will at once condemn this as being impossible in practice. Where the impossibility, or even difficulty, exists, we cannot see, whilst its justice and simplicity appear to us beyond question. He further says that the result would be that "a person possessing the photograph of a cherished—perhaps dead—friend would not be at liberty to have it copied without permission," &c. No; precisely not. That is just the aim of copyright; to prevent any one, friend or foe, from copying without permission. If the real or assumed friend might so copy, how shall he who is no friend be prevented? Mr. Bassano assumes many difficulties: for instance, the owner of the original negative and copyright might be a "hundred miles away." Is there no postal service? He "might be dead." There are generally representatives of his estate into whose hands his negatives have passed. Or he might be "jealously disinclined to give the required authority." Well, even the dog in the manger might be coaxed by a tempting morsel. Mr. Bassano next deals with a literal point, which, we think, he somewhat strains. Quoting a passage from the new Bill, which says that where a photograph has been made to order, and for a valuable consideration, the proprietor of the copyright shall not sell, &c., any copy of the photograph without consent of the person who commissioned it, &c., Mr. Bassano thinks this phraseology is not sufficiently clear or accurate. He would substitute the words "print from the negative" for "copy." Mr. Bassano alleges that a "copy of the photograph" is quite distinct from a "print from the negative." So, in one sense, the two are distinct, as a copy may mean a reproduction. But a "print from the negative" might not cover the ground so well as a "copy of the photograph." An enlargement, for instance, is not, and would not be understood as, a "print from the negative," whilst it is a copy of the photograph, and needs to be comprehended in the phrase in question.

Our object here is not to put Mr. Bassano in the wrong, but to illustrate a principle. The provisions of a new Act, which may so seriously affect the interests of photographers, needs the examination, consideration, and discussion of several competent persons. It is so easy for one person, being strongly impressed with one point, to overlook or misconceive other very important points, as we conceive in some respects is illustrated in Mr. Bassano's letter, an intelligent and valuable communication, emanating from one man who takes the trouble, amongst many silent ones, equally interested, to vindicate his profession. If professional photographers have sufficient enterprise and camaraderie to form a guild for self-protection, they may find that in the multitude of councillors there is wisdom, and such questions may be reasonably dealt with.

It is unnecessary to consider in detail the various wild suggestions and comments on photographic copyright which have been made—possibly the wildest, that of his Lordship, given from the Bench, to the effect that it would be necessary for a sitter to purchase the negative of his portrait to secure immunity from publication. The really efficient method is to sit only to respectable portraitists, whose promise that they will not issue copies may be trusted. The only fear then of publication would arise from the class against whom the judge's remedy would be powerless—we mean the unscrupulous photographers who make copies of prints without troubling themselves about the negatives. But who shall escape every peril in life? Whoever becomes celebrated, whether it be for beauty, ability, or crime, must be photographed; and if they decline absolutely to risk the perils of photography, they

risk others they dream not of. The bishop who refused to sit was scarcely adequately or satisfactorily represented by the criminal "with forehead villainous low," whose portrait was scattered broadcast on the strength of a similarity of name. But this was not done by a respectable photographer.

FRENCH CORRESPONDENCE.

EXPERIMENTS WITH VAN MONCKHOVEN'S STUDIO PHOTOMETER—ACTION OF LIGHT ON GELATINE RENDERED INSOLUBLE BY IRON PERCHLORIDE.

Experiments with Van Monckhoven's Photometer.—In accordance with the promise which I gave to my esteemed readers, I feel it my duty to make them acquainted with the results of my experiments with, and investigations into the principle of, the instrument which my learned friend, Dr. Van Monckhoven, proposed to use as a photometer for the studio. As I stated at first, Van Monckhoven has not been at the pains of setting any definite form for this apparatus; he has merely indicated what is the action of light on uranium oxalate, and has given a simple method of verifying that action. No doubt all the experimenters who have wished to verify the statements of Van Monckhoven have first of all set to work in the way which he indicates. This has been my own case; but I was soon led to the observation that the instrument, to act as a correct photometer, must be constructed in quite a different way to that described by the inventor. A close examination of the working of the apparatus—that is to say, of a flask of about 250 cub. centim. capacity, into the neck of which, by means of a caoutchouc stopper, is fitted a tube—has at once disclosed the fact that the action of the light, in reducing the uranium oxalate, continues a long time after the rays of light that fell on the vessel have been cut off. Several hours afterwards, and in complete darkness, disengagement of the gas is maintained, and the index, formed by a small column of the liquid which is isolated in the tube, continues to rise. This forms a serious obstacle to the employment of the instrument during a short period of time, and for several successive observations, when that instrument consists of one vessel only. But the defect might be remedied by setting upon a stand ten or a dozen flasks or bulbs of glass of a smaller capacity—100 cub. centim. would be quite sufficient. Each of these bulbs should be furnished with a neck, to which should be fitted a tube, curved in such a way as to lie in a horizontal position, and these ten or twelve tubes should then be fastened to a graduated panel, the zero point being so arranged as to be as close as possible to the vessel. An index of mercury is brought at each observation to the zero point by means of a moveable wind pipe, and a number of independent opaque shades, each of which is made to cover one of the bulbs, will afford the means of exposing at the time of observation any one of the bulbs to the light, while the others are kept in the dark. Evidently this is a much more complicated apparatus than the one indicated by Dr. Van Monckhoven. The point, however, is to utilize the principle, and consequently to adapt the construction of the instrument so as to maintain the truth of that principle, and not to arrange it for merely one of its phases. My honoured fellow-worker, Dr. Vogel, has pointed out another defect, though I have not yet had an opportunity of corroborating his opinion. This appears to be due to the formation of a large number of crystals in the interior of the flask in consequence of any lowering of the temperature. On account of this phenomenon, he says, a less concentrated solution of the uranium salt must be used in winter when the temperature is low, and hence the sensitiveness of the apparatus will be lessened. This proves the truth of what I affirmed at the outset, that it would be necessary to take account of the temperature and also of the degree of concentration of the solution; also that it would be requisite to discover a simple formula connecting

the temperature with a fixed standard of concentration, so as to lead to a knowledge of the comparative action of light in the unit of time. Now our friend Van Monckhoven, who is nothing if he is not a practical man, knows all this as well as I do, but, at the same time, he is perfectly aware that the greater number of photographers are hardly sufficiently versed in the delicacy of chemical manipulation to be able to use an instrument of this kind with the proper accuracy. Nevertheless, they ought to be practically acquainted with all the details of their profession, and we must therefore avoid placing in their hands an apparatus which they are unable to use correctly. The photometer, therefore, in its present form, is in this respect defective, and it remains for us who are by profession investigators to study the question closely, to look at it from every side, until we have invented an instrument which, acting on the same principle, shall give us a correct measure of the intensity of light. My learned colleague, M. Poitevin, has also indicated numerous applications of the principle of the action of light on bichromatized gelatine, but he himself has not been in a position to carry out these applications so as to make them of value to the practical photographer; in the hands of specialists, however, they have produced results of the greatest importance. In the same way will it be with the photometer—the nascent photometer of Van Monckhoven—it will be improved and transformed until it is able to render great services to photography, but it will always have the name of Van Monckhoven attached to it.

A Printing Process by Means of Insoluble Gelatine afterwards Rendered Soluble by the Action of Light.—Since I have had occasion to mention the name—a name never to be forgotten—of Poitevin, I should like to say a word on that gentleman's special process depending on the action of light on a layer of gelatine made insoluble by the following solution:—

Water	100 cub. cents.
Iron perchloride	3 grammes
Tartaric acid	1 gramme

Gelatine, with which this solution is incorporated, is insoluble, but ceases to be so in those parts where light is able to act, by reducing to its natural state the iron compound. I have not myself been able to make experiments on the very interesting reaction here indicated; but as it has been published by a man whose assertion on such a point it would be impossible to doubt, I can at once see very important results that follow from it. I can foresee here a means of producing carbon papers for special purposes; these could be sensitized from the very first, for all that is requisite is to have insoluble pellicles of pigmented gelatine, stored in a dry and dark place, where they could be kept for a long time without deteriorating. With this inverse method of working—I call it "inverse" because the action of light produces an effect quite opposite to that which it has when the gelatine has been sensitized by bichromate—we ought to be able to arrive at results of quite an opposite kind to those of the ordinary processes. Adopting this method in the Woodburytype process, as pointed out by M. Boivin, we might leave the film of gelatine in contact with the glass plate over which it had been flowed, and expose this upper surface against the negative. The gelatine, which is at first insoluble, would become soluble to a depth corresponding to the greater or less transparency of the negative. Opposite a very transparent part a depression would be formed much deeper than in a place opposite a comparatively opaque part. The transparency produced would be positive; a moulding taken from it would be negative, and this, in its turn, would give the ordinary metallic plate of the Woodburytype. With a positive transparency a print could be taken serviceable for the first moulding. When applied to special kinds of carbon printing, or for the reproduction of line drawings, the layer of gelatine must be very thin, and not highly

coloured, and then the following action takes place: if it be exposed beneath a positive—for instance, a pen and ink drawing on thin paper—the light acts through all the translucent parts, but not on the parts beneath the lines. When sufficiently printed, it is only necessary to place it in hot water, and the lines alone will remain visible; the whole of the ground, which has been acted on by the light through the white paper, has become soluble, and has been washed away by the hot water. Hence we have the means of obtaining as a direct positive the reproduction of a drawing in black lines on a white ground. This application of the process appears to me to be of great importance, and to have a successful future in prospect. I believe, moreover, that in this country it will soon be worked on a larger and commercial scale. The experiments that it is my intention to make will, I hope, have practical results, which may be of great service to those endeavouring to work out such applications, and I shall be glad, so soon as I have completed them, to lay those results frankly before my readers. I have already discovered another means of applying this action to the production of the negative copy of a line drawing on a sheet permeable only in the parts corresponding to the drawing, and rendering by pressure the exact reproduction of the original drawing. The conclusion to which we are led by the arguments of this letter is: all honour to those who lay down the great principles! The discovery of the practical applications to which those principles can be put is merely a question of time. All honour to such men as Van Monckhoven and Poitevin!

LEON VIDAL.

PRESS OPINIONS ON PHOTOGRAPHIC COPYRIGHT.

Mayfair comments as follows on what it terms Photographic Licence.

The question has become one of public interest; and Rosenberg is but one of a class of alleged libellers, and Mesdames West and Langtry but two of many ladies who, courting notability, have found that the gratification of this vanity has brought with it its own penalties and subjected them to coarse attack or unfounded and infamous suggestions. The husband of one of the ladies has, indeed, come forward and bewailed his position. He has seen what has been said for the last twelve months. It has been said in every form and way. There have been delicate hints. There have been plain statements. There has been sermonising. There has been satire. There has been scandal mixed with friendly advice, and coarse invectives accompanied by improper and unfounded insinuations. But all these have been but different forms in which public opinion has put the same fact—that it is not seemly that an English lady moving in private society and holding no official position whatsoever should put herself on a level with ballet-girls, actresses, and the favourites of the *demimonde*. The ladies who have done this, and the husbands who permit them to do so, cannot claim the excuse of ignorance or palliate themselves by saying that their present position is the result of a single false step. The bad practice has steadily gone on, and yet it provoked a storm of criticism from the very beginning. Soon after the portraits of these beauties were in the market, and were sold over the counter at tenpence a piece to every gallant attorney's clerk or gay young draper's assistant, the Press took the matter up and delicately gave a hint which it was hoped would be at once acted upon. The hint was not taken, and the photographic exhibition, on the contrary, became more numerous and more piquante. They soon ceased to be simple portraits. Every excuse was taken to present the beauty in a new attitude and a new costume. In one, her neck was seen to perfection, in another her arms, and in a third her position in a swing would exhibit a generous outline to the best advantage. Every day produced some new evidence that beauty was many-sided, and that photography was able to cope with all its attractions. Again the Press made itself heard. It spoke now in a doubtful voice. It took its place as a *Censor Morum*, and appealed to good taste and the reticence which had hitherto accompanied the blameless life of a modest English lady. The appeal was not responded to, and the mischief multiplied. The evil grew, and grew in two different directions. It affected the social position of ladies, and it injured the tone and character of the

English Press. It made vulgarity fashionable, and it made the abuse of vulgarity fashionable. The shop-windows were full of half-draped beauties, some professional and some private, amongst whom it is difficult to believe that a lady would allow herself to be placed, and the book-stalls were covered with pamphlets, newspapers, and reviews, in which it was distinctly said that indelicacy was coming into vogue, and that it was very difficult to distinguish between an English lady and a foreign harlot. In most cases such an assertion was grossly untrue, but in some it seemed as if it might be not without some foundation. Things, indeed, having gone so far, soon went further. The next step in this race for popularity was for ladies to make their appearance at trials where the question was whether modesty had been outraged and women seduced. Over and over again the judge from the Bench would give a hint, which was treated with the same indifference as the remarks of the Press of the photographs of the beauties. It soon became obvious that English women were beginning to have a taste for publicly displaying themselves in scenes where hitherto it had been thought they should not even be supposed to be present. Soon the courts of Westminster, when a divorce case came on, were as crowded as a morning performance at a theatre, and the windows of the photograph shops produced a new series of novelties. Hitherto the tenpenny beauties of fashionable life had been married ladies, and in many cases ladies of the aristocracy; but now an advance was made. Young girls in private life were done 'in cabinet form,' and exposed for view with Christian and surname printed under, at two shillings a portrait, or when the portraits got soiled, tossed, or out of fashion, at eighteenpence. It seemed, indeed, that a bad habit, based on the gratification of frivolous vanity, was to undermine the modesty which for centuries has been the pride and glory of English girls.

It is true there was an excuse. It was said that the advertised beauties could not help themselves. Photographs must be taken, and, once taken, what could the beauty do? It was not her fault that her good looks rendered her a saleable commodity. The photographer had the money benefit, and the general public got the advantage of cheap beauty. The answer was to a certain degree conclusive; though, indeed, it was obvious that some of the photographs were taken for the very purpose of giving the greatest gratification to the greatest numbers. Still the Beauty said that she could do nothing, and she not only said it but thought it, and all the world thought so too. It might, indeed, be well that ladies who attend the law-courts should know a little law, and that women who gain a reputation from their photographs should learn the conditions under which they are produced. Happily, the rules are very simple, and can be stated without the use of technical language. Any lady who gets her photograph taken, and who pays for it, owns the copyright in the negative. She has paid for it and it is hers. The photographer may keep the plate, but he keeps it for her benefit and not for his own, or at least only for his benefit in so far as he will be paid for the copies she may subsequently order. And he must not sell a single copy without her leave. If he does so her (or her husband) may proceed against him before a magistrate and recover a sum not exceeding £10 for every copy so sold. If, however, she is photographed for nothing, then the artist has the copyright, and may reward himself by selling the portraits to the public.

Mr. Thomas Fall, in the *Daily News*, says:—

SIR,—A quotation from the *Solicitor's Journal* was published in your yesterday's issue respecting the copyright in photographs. Though in the main correct as an interpretation of the Act of 1862, it is misleading to the public as regards their transactions with the portrait photographer, and I have no doubt you will allow me to state what is really the contract between the one and the other. The photographer engages to supply a certain number of portraits for his sitter at so much per dozen or so much each, and he produces the negative without any charge to his patron. The negative being merely his means for supplying the portrait, cannot be in any sense the property of anyone but himself, and in this particular I say the paragraph is misleading. The words of the Act are likewise very loose and ambiguous, so much so that I may say no photographer in London is in the habit of "executing photographs for or on behalf of any person for a good or valuable consideration," as it must be admitted that the charge for a dozen copies cannot possibly be said to constitute that "valuable consideration" which would include the ownership of the negative.

With regard to the question raised by the Copyright Commissioners' recent report—"the control over the multiplication of copies"—I may say that no respectable photographer ever permits portraits printed from his negatives to be issued to the public except at the request or by the permission of the sitter.

A letter in the *Daily News* says:—

Will you allow me to point out that your correspondent, Mr. Falls, has fallen into some confusion between the property in the negative and the property in the copyright of the photograph? The negative, of course, remains the property of the photographer, but under the Act of 1862 the person who is photographed, or more correctly speaking, enters into the contract, has the property in the copyright, and therefore he alone can authorise copies to be multiplied from the negative. I take it therefore that any photographer who should permit any person without such authority to obtain a copy of the photograph would be acting illegally and would render himself liable to a penalty. I only refer, of course, to the ordinary case, where there is "a good and valuable consideration" given for taking the photograph.—Your obedient servant, A BARRISTER.

Whenever the subject of photographic copyright is discussed in the public press, a letter is sure to appear signed by a Mr. Leighton, dating from the Royal Institution. This gentleman assuredly bears no good will to photography and photographers, as he styles it "a chemical result, often abortive." In what the result is "abortive" we do not profess to understand. How photography was favoured by Lord Westbury, or in what Mr. Foster changed his views, the following letter which appeared in the *Times*, does not show.

SIR,—The right to one's face" has been so often discussed in the *Times*, and the evils of the present state so fully exposed, that it is hoped the propositions embodied in the report before the House, at least as regards photographs, may become law. As a member of the Copyright Committee that sat for two years at the Society of Arts, under the presidency of Sir C. Eastlake, I must say that the artists were against such extensive powers being accorded to a chemical result (often abortive). At the Antwerp Congress of 1877, I used all my power to have the matter rectified, as I believe has been done in the Belgian law, and I see by the *compte rendu* of the Congrès International de la Propriété Artistique which I have just received from the Imprimerie Nationale that the subject has been met. The committee consisted of the first artists and jurists in France, where such an abuse could never have occurred, as it has here. With the Code Napoléon and a public prosecutor, such matters meet with prompt and summary condemnation. Our present state of the law was mainly due to the late amiable secretary of the Society of Arts, when photography was less practised than now. Mr. Lo Neve Foster, being on the Council of the Photographic Society, felt bound to do all he could for it, and, having the drawing up of the report, prevailed upon Lord Westbury to favour photographers, though before his death I believe Mr. Foster had changed his views—at least as regards sun portraits.—Better have no legislation at all than give the right to one's face to any one save the sitter.—Yours ever,
Royal Institution, Oct. 28. JOHN LEIGHTON.

In the following letter to the *Times*, a photographer naturally enquires why ladies sit so often in fresh costumes if they object to publication:—

SIR,—In your article of to-day on the *Town Talk* libel case, I think you were a little unfair in your remarks upon photographers selling publicly the photos. of our fashionable beauties, &c., without their consent. I think you must allow that ladies cannot much object to having their photos. exposed for sale when they go again, and in some cases several times, to the same photographer to be taken in another position, well knowing that he will offer, as he did on a former occasion, this new photo. for sale. I should say that most photographers would take this as a tacit consent on the part of their fair client to his offering the photo. for sale in shop windows, and I think with justice. This, I venture to say, to a great extent is what has made the photos. of our fashionable beauties so common, and evidently, if they desire it, the remedy is in their own hands.—Yours truly,
October 28. PHOTOGRAPHER.

The Queen says:—

The recent trials for libels against two ladies have resulted in the conviction of the defendant, and his sentence to imprisonment for eighteen months. Convictions for libel are, however, matters of such ordinary occurrence, that this one has only excited special interest because the names of two ladies so well known in society have been by the trial brought before the public with a greater than usual prominence. From any ordinary trial of libel the public can learn but little; but from this trial the public has become definitely aware of an evil that has hitherto lurked unsuspected in the result of a visit to our photographer.

The fact that photographs of these ladies were sold in large numbers, and that they were exhibited in shop-windows to be gazed at by whatever crowd chose to assemble, was made the foundation upon which the libel was founded. Mr. Watkin Williams told the Court that his client was desirous of stopping the publication of the photographs of his wife, but that he found it was impossible for him to do so in the present state of the law. The other prosecutor probably also shared in this desire; and the impossibility of stopping the sale of the photographs of these ladies must have been very painful to their husbands. Few men, we should imagine, could enjoy the idea that the portraits of their wives, in various costumes and attitudes, were sold, or that any man who chose to spend a shilling or two could become possessed of their "counterfeit presentments."

It appears, however, that they have no remedy in the matter, and that as the law stands, anyone not purchasing the negative of his or her own photograph, and thereby acquiring the possession of its copyright, may be subjected to the same penalty of publicity. We have, indeed, heard, even in the privacy of quiet middle-class life—far removed from the "fierce light that heats upon" the leaders of fashion and society—that persons have been able by purchase to obtain copies of photographs of others in whom they were interested, even though they had not liked to ask for, or perhaps had been refused the gift of, a copy from the hands of the original. In this way, enthusiastic admirers secured the portraits of their favourite clergymen; grateful patients obtained the likeness of the physician or surgeon who had brought back the health of whose return they had despaired; admirers of particular statesmen enriched their albums with the "heads" of the objects of their admiration; and it has been whispered that, now and then, lovers possessed themselves by these means of representations of those who were dear to them. We have always thought that, in the cases of quite private persons, the use of this power of getting photographs was rather of the sort which is called "taking a mean advantage;" but, in the case of very well-known and public characters, we have generally regarded the matter in the light of a speculation indulged in by the photographers. Indeed, many persons whose public position makes it likely that strangers would choose to have their photographs, are importuned to "sit," and are presented with some copies of their cartes or their cabinet portraits, in order that they may consent to have their photographs sold as a "venture" by the photographers. It appears now, that if they once allow their portraits to be taken, they have no power to stop the multiplication and sale of them. When one recollects the hideous renderings of one's face that are sometimes produced as the result of photography, one shudders at the possibilities that have been thus laid open before many.

Fortunately for the majority of the sober citizens and dames who constantly trust themselves to the limning powers of the sun, the "expression" of the sitter is generally a matter of no moment whatever, except to himself or herself, or half a dozen or so of more or less partial friends. The photographer may register the sitter as "No ——" and may inform all whom it concerns that copies are always to be had. But few indeed want copies, and, no doubt, after the lapse of a reasonable amount of time, the "negatives" are reduced to a non-existent condition, so far as the photographs are concerned.

But, every now and then, a man or woman becomes observed beyond the crowd, distinguished for something good, or notorious for something evil; and then comes the fortunate moment of the photographer who has been, as he considers, lucky enough to have been employed to reproduce the portrait of the "victim."

It certainly falls to the lot of but few, comparatively, to be among those whose photographs are desired by collectors. Fewer still care much whether their photographs are in demand or not. But it does seem hard that, if a person should desire

that his or her photograph should not be hawked about in the open market, he or she, in the present state of the law, should be unable to prevent this undesired publicity, except by the purchase of the negative of the portrait.

As it is now, it is well to remember that, if we desire to retain in our own control the publication of our photographs, we must make a bargain to that effect with our photographers, and must have clearly and legally conveyed to us all rights in the negative and photograph. Whether this consideration will have any deterrent effect upon the general public remains to be seen. But it is at least as well to bear in mind a peril of which most folks have hitherto been entirely unwitting.

Mr. Bassano writes to the *Times* as follows:—

SIR,—My apology for begging you to apportion sufficient space in the columns of the *Times* for the insertion of this letter is the importance, and, I may add, popularity, of the measure to which it refers, and the urgency arising from the near approach of the period when that measure may become law. That part of the proposed new Copyright Bill which refers to the copyright in photographs is, in my opinion, so ambiguous and, in particular, clause 34 shows such an imperfect knowledge of the subject, that I am afraid, with all deference to its compilers, that upon the first practical test being applied to it, its defects will become apparent, and reconstruction rendered inevitable. The clause commences with the words:—"The copyright in a photograph shall belong to the proprietor of the negative from which the photograph is printed." An experienced photographer will at once condemn this as being impossible in practice—its effect would be that a person possessing the photograph of a cherished, perhaps dead friend, would not be at liberty to have it copied, enlarged or diminished, without first having obtained the permission of the photographer who produced the original negative; and he, the photographer, might be dead, a hundred miles away, or jealously disinclined to give the required authority; it would be manifestly impossible to comply with this condition, and its immediate alteration would be rendered necessary.

The next, and as it appears to me fatal, error is, that the clause proceeds to deal with a "copy of the photograph" when it intends to legislate for a print from the negative. These are two distinct things, but the distinction is not established in the clause. By quoting this part I shall be able more clearly to show what I mean:—

"Where the *photograph* has been made on the order of any person for a valuable consideration, the proprietor of the copyright shall not be entitled to sell, expose for sale, or exhibit any *copy of the photograph* without the consent of that person, and that person shall have the same right of preventing the selling, exposing for sale, or exhibition of any *copy of the photograph*, and, if the copyright is infringed, of taking proceedings in respect of the infringement, as if he were the proprietor of the copyright."

The words in italics are the fatal words which would render the clause wholly inoperative. The first word, "photograph," should be altered to "negative," and the words "copy of a photograph," in each subsequent instance, should be replaced by the words "print from the negative."

With these corrections the meaning of the clause would be perfectly intelligible, both to the photographer and to the public; whereas if it should pass into law in its present state, the former will find many loopholes whereby he may legally evade the penalties attached to it. For instance, if it remains uncorrected, he may argue that as he is the proprietor of the negative he may make whatever use he pleases of it, and that he cannot be prevented, because in no other part of the clause is his power annulled, the subsequent sentences simply referring to copies of the photograph, and not to prints from the negative.

Now, it may not have struck the compilers of this clause that copies of a photograph are not prints from the (original) negative. A person sits to a photographer and receives twelve photographs; one of these photographs he sends to another photographer, and requests him to make twelve copies from. In due course they are sent to him, and they are veritable "copies of a photograph;" but they are not prints from the original negative, and these latter, it is evident, are what the clause intends to deal with, although they are misnamed "copies of a photograph." I take it that it is thought desirable to prevent the multiplication of prints from the negative in the possession of the photographer who has made it unless he shall have previously obtained permission so to multiply them; but the clause

as it stands will not do this, as it simply prohibits the issue of "copies of the photograph." It appears to me, therefore, that the clause should be altered to the following effect:—

"The copyright in the negative shall be the property of the proprietor of the negative; the copyright in the photograph shall be the property of the person for whom it shall have been produced, but to be only available for private use, and not for the purpose of gain by publication. Where the negative has been made on the order of any person for a valuable consideration, the proprietor of the copyright shall not be entitled to sell, expose for sale, or exhibit any print from the negative without the consent of that person, and that person shall have the same right of preventing the selling, exposing for sale, or exhibition of any print from the negative; and if the copyright is infringed, of taking proceedings in respect to the infringement, as if he were the proprietor of the copyright."—I am, Sir, your obedient servant,
ALEXANDER BASSANO.

25, Old Bond Street, Nov. 3.

Correspondence.

THE FLYING SWALLOW.

SIR,—I venture to suggest that if Mr. Gale were to bring the swallow negative to the meeting of the Photographic Society on Nov. 11th, it would be an interesting exhibit, and decide the question.—Yours, &c.,
SCEPTICAL.

MEDALS AT THE EXHIBITION.

SIR,—Do you ever remember a photographic exhibition without numerous complaints respecting the medals and awards, the hanging, the time allowed as being too short to get them in, &c.?

The clique of exhibitors are like a lot of spoiled school-boys, who, having always taken the prizes, cry out because some one else has gone to the top of the class and they have only got honourable mention. Quite enough! They have monopolized the medals at all the exhibitions long enough, and methinks, perhaps, with the work of other peoples' brains, for, in many cases, the pictures have been the out-put of the employés of the establishments, and not the masters at all. I hail the awards with pleasure as showing that there is a likelihood of the blind patronage of the awards to the clique being at last broken through, and giving merit a proper recognition. No more gullery, black varnish, &c., or clouds added, that most likely were made by some one else, or breaking waves, said to be moonlight effects, when they were taken in a strong sunlight, &c.

I am not a disappointed exhibitor—never was, and never intend to be; I have something else to do. Neither am I an employé who considers he has been slighted by not having his work appreciated.—I am, sir, a hater of humbug, and yours truly,
JAMES SYRUS TULLY.

PS.—Might I explain that in my last I referred to the eminent photographers not attending meetings to show the way they did their business? I did not mean their trading, I meant the way they made their negatives, and how they arrived at the magnificent results.

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The usual monthly meeting of this Association was held on Thursday evening, the 30th ult., in the Lecture Room of the Free Library, William Brown Street, Mr. J. H. T. ELLERBECK, Vice-President, in the chair.

The minutes of the previous meeting were read and passed and Mr. Kenneth Bean was elected a member of the Association.

Mr. W. H. KIRKBY exhibited some negatives, with prints from them, to show the capital results he was getting from the gelatino-bromo plates which he prepared by Captain Abney's process described in the *British Journal of Photography* of 22nd May last. He (Mr. Kirkby) handed round two prints and their

corresponding negatives, the one being a Swan's plate and the other one of his own make. He had asked the Secretary to expose them simultaneously on a landscape; and the members could judge for themselves whether they would work a process which produced such good negatives and was so easily followed.

The Rev. H. J. PALMER said the negative made by Mr. Kirkby was, he thought, as near perfection as could be obtained. The plates were free from granularity, and without blemish of any kind, and of the two, he gave the preference to Mr. Kirkby's negative.

A discussion on the manner of preparing the plates was taken part in by Mr. Peter Mawdsley, Mr. Ellerbeck, Mr. Kirkby, and others.

Mr. G. BOOTHROYD exhibited Mr. Harrison's very ingenious rapid shutter, which has been previously exhibited and described in the *British Journal of Photography* by Mr. A. Brittlebank.

Mr. DAY exhibited a purchased gelatine plate covered with crystals, the negative being also full of pinholes. The crystals were evidently glass incorporated in the film, the plate having probably been laid face downwards on a glass-cutting table.

Dr. KENYON exhibited and explained the working of one of Rouch's patent 12 by 10 cameras.

A lantern exhibition closed the proceedings of the evening, the transparencies having been taken by Mr. Weber from the negatives of several of the members.

It was announced that the associated *soiree* of the literary, scientific, and art societies of Liverpool would be held in St. George's Hall, on Wednesday evening, 10th December. Members wishing to exhibit objects of photographic interest were requested to communicate with the Secretary.

The meeting was then adjourned to the 27th instant.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

The first monthly meeting of the above Society for the session 1879-1880 was held, by invitation of W. Dakin, Esq., the originator of the present Society, at his residence, Holly Bank, Nether Edge, on Tuesday evening, November 4th, when the members sat down to a sumptuous repast.

After tea, the chair was taken by Councillor THOMAS FIRTH, Esq., the esteemed President of the Society, and

A very interesting paper was read by Mr. DAKIN, on "The Choice and Use of Photographic Lenses," in which the writer advocated the use of lenses specially adapted to the work required of them, and disapproved of the endeavour to make one lens answer all purposes.

An instructive discussion followed. Various novelties in apparatus, &c., were exhibited; also a choice selection of stereo slides from gelatine dry-plate negatives, the work of one of the members, which were much admired.

The conversation then became general, and, with music, &c., an enjoyable evening was brought to a close.

J. TAYLOR, Hon. Sec.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The first meeting of this Society for the ensuing session will take place on Tuesday next, Nov. 11th, at the Gallery (Photographic Exhibition), 5, Pall Mall East, at 8 o'clock, when the medals will be presented, and a paper will be read by Mr. Leon Warnerke "On Photometers."

CHRISTMAS CARDS FOR PHOTOGRAPHERS.—Messrs. Reeves and Hoare have favoured us with some examples of grotesque pictorial cards illustrating photography for distribution for advertising purposes by photographers. The subjects are amusing, the designs good, and the work well done. We have no doubt that they will be found useful for distribution.

STEALING A PHOTOGRAPHIC EXHIBITION.—At the Thames Police Court, a few days ago, Francis Sales, a butcher, was charged on remand, before Mr. Lushington, with stealing a photographic exhibition, value £25, the property of William Johnson, living at 5, Sydney Street, Mile End, Old Town. It appeared that the prosecutor used to gain a living by exhibiting his show in the street. On Wednesday morning, the 12th of March, he had occasion to leave home on business, and when he returned at night he was surprised to find the prisoner, who was a lodger, gone, and also his show. About a week ago he met the prisoner

at Temple Mills, and gave him into custody. A previous conviction for felony was proved against the prisoner, and Mr. Lushington committed him for trial.

ZULU PHOTOGRAPHS.—The London Stereoscopic Company, of which Mr. Alderman Nottago and Mr. Kennard are the proprietors, have taken the preliminary steps in an action in the Supreme Court for slander against Sir Charles Whetham, the Lord Mayor, for expressions used in his magisterial capacity on the recent hearing at the Mansion-house of a summons against a shopkeeper in the City on a charge of selling and exhibiting indecent Zulu photographs. The Lord Mayor, through his solicitors, has accepted service of the process, with a view, according to his solicitors' explanation, of having "an opportunity of enlightening the public on the true facts of the case, and justifying the course he has taken."

THE TACTICS OF PHOTOGRAPHERS.—Photographers sometimes seem to regard themselves as chartered libertines in the matter of multiplying copies of the portraits they have been employed to take. In May last a lady had her portrait taken by a well-known firm of photographers, who were duly paid for their work. In August this firm sent to her a copy of this portrait on porcelain, mounted in red velvet, and which they declared to be "of more than average merit as a work of art." They added that if the lady should decide to purchase it, the price would be five guineas. The lady's husband, being fearful that it would be exhibited in the photograph shop, offered three guineas for it. This the photographers declined, and it was then pointed out to them that they ought not to have made such a copy of the portrait they had been paid to take, without having first consulted, and obtained the consent of, the lady's husband. To this they replied as follows: "We are sorry that you think us wrong in having finished such a picture without having first consulted you in the matter, but our experience is that unless people see what can be produced from their own photographs they do not give orders. We could show you dozens of letters thanking us for sending similar pictures for approval, and in many cases a second copy has been ordered." In this instance the lady's husband brought the matter to a close by requesting that the copy might be effaced, which was done; but it is to be presumed from their letter that so long as this firm finds that people "do not give orders" without seeing "what can be produced," so long will they go on making copies of the portraits they take without first obtaining the consent of the originals.—*Vanity Fair*.

USE OF PHOTOGRAPHY IN WOOD ENGRAVING.—In the practice of the ordinary method of wood-engraving, the artist whitens the surface of the block and makes his drawing thereon with India ink or pencil. The engraver then cuts upon the drawing, endeavouring to keep in mind the general effect of the original; but the latter is of course gradually obliterated as the work of cutting proceeds. To this obliteration of the original drawing is probably due a part of that loss of artistic effect in the finished engraving of which draughtsmen are apt to complain. The facilities offered by photography are now, however, being used by engravers and draughtsmen to assist in the production of better engravings. Instead of drawing directly upon the wood, the artist now makes his finished picture upon paper, which is then photographed upon the wood in exact *facsimile*; the engraver then proceeds to cut the photograph, and during the whole time of cutting he has before him the original paper drawing, to which he may refer for assistance in his endeavour to maintain and reproduce the spirit and feeling of the picture.—*Scientific American*.

To Correspondents.

THE YEAR OF PHOTOGRAPHY, 1880. In order to facilitate our labours in preparing the YEAR-BOOK OF PHOTOGRAPHY for next year, we shall be greatly obliged to those of our readers who can favour us with brief practical papers on subjects arising in their experience, so that our annual may be, as it is designed, a complete record of the progress of the year, and a trustworthy practical guide for the future.

RETOUCHING VARNISH.—We have several applications for details of the retouching varnish mentioned in "Looking Back." To these we shall respond when the information reaches us. It will be necessary, however, for all applicants to send a stamped and addressed envelope.

JOHN WATKINS.—Aniline red of different kinds can be had of most chemists. Probably all the London photographic chemists would supply it. Failing this, Judson's dyes will answer very well for the purpose.

H.—We do not know whether the firm of Dollmore and Bullock now exists, or the whereabouts of any representative of the firm.

S. SENATO.—Your negative reached us in fragments from imperfect packing, hence we were unable to examine it. So far as we could judge by some of the fragments, the trouble from which you are suffering is known as matt silver stains or oyster-shell markings. These are chiefly due to the quality of the collodion, which is of a tough, horny, repellent nature. Ripeness from age is the only corrective to the collodion. It may be mended by adding a little old and powdery collodion. But so long as the collodion remains horny and repellent it will occasionally give such stains. Immersing the plate immediately the collodion is set, before it becomes in any degree dry, will help matters a little; or redipping the plate in a fresh 10-grain bath before development will help matters. Remember, please, that it is of no use whatever to transmit a negative through post unless it be packed in a moderately strong box, as it is sure to be broken. Yours, being placed between two slight pieces of board, were completely smashed.

S. PERRY.—To enable us to help you, an accurate reference should be given. There is no article on Development Printing on p. 24 of the YEAR-BOOK for 1878, hence we have no idea of the method to which you refer. Judging from your allusions that you tried to get an enlarged image on drawing-paper by the light of a paraffin lamp with ten minutes' exposure. So far as we can judge without further information as to your proceedings, there was no chance whatever of success. You might obtain an image on a collodion plate so, but not on sensitized paper. A collodion transfer may be so obtained. In printing by development on paper, after development the print should be thoroughly washed before fixing, otherwise the hyposulphite will be decomposed, and the elements of sulphur toning and subsequent fading produced.

J. JACKSON AND OTHERS.—We will forward the details of the Retouching Varnish mentioned in "Looking Back" as soon as we receive the information from our contributor.

H. COX.—Your letter with addressed envelope duly received, and shall have due attention. Regarding the missing stamp, about which you are "positive," we can simply tell you that it was not in the letter when it reached us.

ENLARGER.—There are various formulæ in which acetate of lead is added to the developer. Here is the one for developing paper prints about which you enquire, as being used in the Belgian War Office. Prepare stock solutions of—

A.—Acetate of lead	1 part
Water	100 parts
B.—Gallic acid	1 part
Alcohol	8 parts

To 4,000 parts of water 50 parts of solution A and 8 parts of solution B are added (if the weather is warm, or the prints have been over-exposed, a little acetic acid may be added with advantage), and the mixture is filtered into a large dish. The prints are immersed one by one, and constantly moved about, to ensure the even action of the solution. The detail gradually strengthens, and, after about a quarter of an hour, appears of a good black colour. They are then removed to a bath of hyposulphite of soda at 30 per cent., and remain in it with constant movement for ten minutes or a quarter of an hour, and are then well washed with several changes of water. No toning is necessary, but, if required, the prints can be toned in the ordinary way. The paper for such development is prepared as follows:—Thin Steinbach Sax paper is salted by floating it for one minute on a solution composed of—

Chloride of ammonium	2 parts
Citrate of soda	2 "
Water	100 "

Sufficient citric acid should be added to make the solution just acid. The paper is then dried, and may be kept for use. To sensitize it, float for three minutes on a bath containing four or five per cent. of nitrate of silver rendered acid with citric acid. This operation and the drying must be performed in a perfectly non-actinic light, as the paper is very sensitive. The exposure under the negative varies from a few seconds to one or two minutes, according to circumstances.

JAMES MAYCOCK.—You will find advertisements in our business columns relating to businesses offered for sale almost every week.

ROBERT SYMONS.—Your photograph of the mirage is on view at the Exhibition, and will be noticed in the NEWS in due time.

EDWIN S. LAUDER.—You will find an article in a recent number giving full details. In the NEWS of September 12th, p. 435, a detailed article appears. Should you require further information, let us know.

Several correspondents in our next.

The Photographic News, November 14, 1879

PHOTOGRAPHY IN AND OUT OF THE STUDIO. EXHIBITIONS AND EXHIBITORS—GELATINE DEVELOPMENT AND A NEW PHOTOMETER.

Exhibitions and Exhibitors.—Mr. Tulley's letter, in which he compares grumbling exhibitors to spoiled school-boys, has a good deal of truth in it. "Do you ever remember," he says, "a photographic exhibition without numerous complaints respecting the medals and the awards, the hanging," and other matters? We frankly say that we do not, and having had some experience of hanging and exhibiting, judging, and medalling, we feel impressively the truth of Mr. Tulley's statement. Nevertheless, we should be sorry to have done with grumbings; all that is necessary in connection with such outcries is that they should be regarded as inherent to such things as an exhibition, and must not be rated above their proper worth. Our neighbours on the Continent are very fond of quoting the well-worn sayings about an Irishman being never at peace but when he is fighting, and an Englishman never contented but when he is grumbling; and perhaps if we were to hear these words in mind a little more, we should be less surprised at the demonstrations photographers make at the period of the Exhibition. In the course of our experience we have never met with a contented exhibitor; we might even say that we do not even know of a contented medallist. The hanging committee usually come in for most of the blame; the enraged exhibitor looks about for somebody to wreak his vengeance on, and these are naturally his victims. A fault, real or supposed, has been committed, and in the exhibitor's eyes somebody ought to be hanged. What more natural than to choose those designated as the hanging committee? But worse than the enraged exhibitor is the injured exhibitor. The former tells you plainly what there is wrong—that you have only hung five out of six of his pictures on the line; he has it out, and has done with it. But the injured exhibitor is never frank with you. There is a canker worm at work about him somewhere, but you can't find out where. He has a catalogue of wrongs, and although members of council and executive officers come and go, his grievances go on for ever. The medallist, again, complains that although he has got a medal, he has not received it for a particular picture which he is quite sure is the best of its kind; and yet a brother photographer who has been awarded the medal for this latter branch of the art, has an exhibit of a decidedly inferior character! This is no exaggeration, but what came under our notice not five years ago. Two photographers, living in the same town, sent up, both of them, very charming work to the exhibition. They both received medals, but for pictures of a different class. The medals were of equal value, and one would have naturally thought the recipients would have been gratified. No so; the one who had the landscape medal wanted the one awarded to his brother for groups; but probably if the awards had been changed, there would have been just as much grumbling. It is well, we hold, that there should be a change made every year both in the hanging committee and the judges, and there cannot, of course, be any excuse for the non-fulfilment of rules on the part of officials. Whatever is promulgated as to the conditions of the Exhibition should be rigorously adhered to, or any alteration made known immediately. At the same time, it must be remembered that those who are entrusted with the duty of hanging or awarding are men of proved integrity, and have a very thankless task imposed upon them, a task which many refuse to perform under any conditions. Under these circumstances, it is somewhat puerile on the part of an exhibitor to cry out that, because of some arrangement or other that is distasteful to him, he will henceforth never contribute to an exhibition. It is very like telling a Member of Parliament with whose opinions you have held for some time, that because he has not pleased you in one particular

you will never vote for him again. Generally you may agree with him, but because on one occasion he runs counter to your prejudices, he is out of favour for ever more. Fortunately, the Photographic Exhibition does not depend upon the humour of any individual, and fortunately, too, the benefits that accrue to an exhibition, small as they may be, outweigh any inconveniences that accrue to him. Every year the Exhibition is becoming more popular. It has now been carried on successfully so long that it has become at last one of the features of the "little season" in London. The Press, all round, give notices as a matter of course, and have not to be "invited" again and again to do so. That the gathering might be conducted with still more spirit and become still more popular, we do not deny; but as it is, those who contribute to the collection never get so good an opportunity of displaying their work. To the professional photographer the result is that his name becomes more widely known; well-to-do visitors, both from town and country, look at his work and criticise it—visitors to whom otherwise he might never be known. Amateurs, on the other hand, have the satisfaction of seeing their work placed side by side with the best in the kingdom, and are thus enabled to judge very well of their skill and success. It is better than all the criticisms in the world to place your picture alongside that of masters in the art. There is then no need for some good-natured friend to point out your perfections or shortcomings, which become at once apparent.

Gelatine Development and a New Photometer.—Photographic Societies are about to resume their sittings for the season, and we sincerely hope that the session may prove an interesting one. There are many subjects that may be discussed with advantage during the forthcoming months, and one of them is the development of gelatine plates. Any photographer of experience who would detail his *modus operandi* whereby he watches and controls development will add much useful knowledge to what we already possess on the subject, and will be welcomed more heartily than usual by his brethren. Most of us have had some experience with gelatine plates, have prepared them, exposed them, developed them, and secured thoroughly good pictures by their aid. But with many, it is still as it was with carbon printing a little while ago. We had no difficulty in securing time after time successful results, but we could not quite ensure every result being perfect. So it is with gelatine plates. There is hardly a photographer who has not a good word to say for gelatine plates, or is not provided with them, and employs them occasionally. But the number who rely entirely upon gelatine work, and who for every score of gelatine films expended can show a score of good pictures, is not, we believe, very large. The difficulty in seeing the result while under development is one of the reasons for this, and if we could only get development well in hand, the greater part of the difficulty would be overcome. We see that Mr. Warnerke is going to tell us about a new photometer he has contrived, and we hope it will be a sensitive one, for we sadly want a measurer of light for our cameras. Photographers have no more idea than they had forty years ago. Daguerreotype was made known in 1839—about measuring the amount of light that enters the camera and impinges upon the sensitive plate. A good photometer would materially assist us in the development of gelatino-bromide plates.

Correspondence.

PHOTOGRAPHIC COPYRIGHT.

DEAR SIR,—I beg to acknowledge the honour you have done me by your notice of my letter to the *Times* newspaper upon the important question of photographic copyright. I conceive it even fortunate that you considered it worthy of editorial comment, because it is quite time the serious attention of the photographic world should be called to this, I may say, momentous subject, and I know of no

better means for the accomplishment of this than that it should be reviewed by the Editor of the PHOTOGRAPHIC NEWS. With respect to that letter, however, your judicial, but at the same time generous, criticism of it makes it only too potent to me how extremely difficult it is for one unaccustomed to public writing to express himself with the lucidity and conciseness essential for the conveyance to others of ideas which are, to his own mind, perfectly clear and unambiguous. If you will permit me, therefore, I shall be glad to have an opportunity to lay before your readers an explanation of some of those points which, it is evident, were not clearly demonstrated in the letter above referred to.

I endeavoured in the *Times* to point out what I considered the fatal errors of the now much discussed Clause 34 of the proposed new Copyright, which may become law during next Session of Parliament; but it is evident I did not succeed in making out my case. I believe it will be admitted that in an Act of Parliament relating to any profession the conditions, expressions, and meaning contained therein should be such as would be drawn up by a committee of experts—*i.e.*, in this instance, experienced photographers—that there should be no ambiguity, neither should there be introduced into any of the Clauses words that might readily bear a different interpretation, to that which was intended; the terms should be clear and true, and such as would withstand the test of logical argument. But it is in these very essential qualities that I find Clause 34 wholly deficient. To prove this, in that part of it where it says, "When the *photograph* has been made to the order of any person for a valuable consideration," &c., I assert *photograph*, taking the context into consideration, is not the proper word to use; I maintain that negative is the only correct term to be introduced in this position, and for this reason. The Clause goes on to say that no copies of the photograph shall be issued without the consent of the sitter; whereas, in fact, it means that no prints from the negative of the sitter shall be issued without permission. So that, as the compilers did not mean copies (or reproductions) of a photograph, but in reality intended prints from the negative, the prohibition, in the first instance, should rest on the negative, and not on the photograph, and, therefore, negative should have been the word adopted.

For a moment, however, as an argument, let us say that photograph is the correct word: how would the subsequent prohibition to issue copies of it prevent the issue of prints from the negative? In no way that I can discover, because the photographer might say to the sitter, "I hand you the photograph for which you have paid me a valuable consideration, and I admit that I am by the Clause prohibited from issuing any copies of that photograph without your permission; but I must remind you that I have the original negative in my possession, and that I am nowhere in the Clause prevented from issuing as many prints from that negative as I please; the Clause simply states that I am not to issue any copies of that photograph which you hold in your hand, but is altogether silent in respect to the negative." Therefore I say "photograph" is an incorrect word to use in this position, and that it should be "negative."

I next take the expression "copy of a photograph," and say that this is also inaccurate. I think it will be admitted that the spirit and intention of the Clause is to prohibit the issue of photographic portraits painted from the negative of the sitter without the consent of that sitter. Now I beg to point out that a photograph is one thing and a negative another: the one is the paper positive resulting from the negative, whilst the other is the matrix or negative itself. Now one might just as well argue that the composed type and the book resulting from it are one and the same thing; if, therefore, you wish to prohibit the usage of the type, why legislate upon the book? It is true you prevent the issue of imitations of the photograph (book),

but you leave the negative (type) unrestrictedly in the hands of the photographer.

Having, therefore, as I hope, proved that a copy from a photograph is not a print from the negative, and that it was the intention of the framers of the proposed Bill to legislate upon the latter and not the former, I think I may fairly say "copy of a photograph" is an inaccurate term to use in this position also.

There is one other question of such vital importance to our profession—the one raised by "Barrister" in his letter to the *Times*, November 8th, as to the ownership of the negative—that I will crave your indulgence for a short space more of your valuable columns to consider it.

I think I may safely say that I shall have the whole of the profession with me when I claim that the worker who has by his innate taste, cultivated experience, and perfected skill, created the negative, shall be the owner of the negative. But though we may as a body be convinced of the justice of the claim of a photographer to be the rightful "proprietor of the negative," yet we must not remain blind to the fact that we have powerful opponents to this opinion. To show this, I will quote that part of "Barrister's" letter which brings it forcibly before our eyes. He urges that an enactment should be passed whereby "every photograph, in the widest sense of the word, including negatives, positive, prints, and copies, shall be the property of the person who, directly or indirectly, orders or requires it to be made for a valuable consideration," &c. It is evident, therefore, from this, that others have opinions diametrically opposite to our own, and it behoves us to state and to stand by our claim if we do not wish it to be supposed that we acquiesce in the dictum enunciated in the above quotation.

Now, sir, though I am in accord with, I believe, the whole of the profession in claiming that the photographer should be the "proprietor of the negative," yet for my own part I would make him so only with limited powers: limited powers in this respect, that though he be the freeholder of the negative, yet that that freehold is only vouchsafed to him by law under the restriction that he shall not make use of the negative to the annoyance of the person whose portrait it is; that is, that he shall not print photographs from it without direct permission. This proposition may appear to be nothing more than is already established as a common custom of the profession, but it must be borne in mind that a new enactment may be repassed during the forthcoming session of Parliament, which will supersede all existing law upon the subject; and with the fact of such opposition as shadowed forth in "Barrister's" letter before us, it is possible that the right we claim may be wrested from our hands. It is therefore incumbent upon us that we should place before our law-makers those views and arguments which we consider ought to have a powerful influence in their determination as to the expediency of fresh legislation upon the law of Copyright in Photographs.

The next point in importance is whether the sitter, who has purchased the photographs, should have the entire and unrestricted copyright in those photographs. I am sorry to differ with you upon this question, but I maintain that he should so possess it, and that such an arrangement would be highly beneficial—and not as you suppose, Mr. Editor, injurious—to the profession at large. It is well known that a large proportion of a photographer's business is derived from enlargements and coloured pictures made from extraneous photographs. What then would be the consequence if the sitter were deprived of the copyright of a photograph which he has placed in the hands of a photographer (who is not the author of that photograph) for the purpose of enlargement, perhaps to the value of a hundred guineas? Why, the result would be that the sitter, from a variety of causes, failing to obtain the required permission, would be unable to commission the work to be executed, and the order would, to the loss of the photographer, necessarily have to be annulled. As a practical man of many years' experience, I can affirm that

this is by no means a strained illustration. To withhold, therefore, the copyright from our clients would, in my opinion, cause immense difficulty and irritation, and would saddle the public with a most irksome and unnecessary prohibition, resulting eventually to the serious injury of photographers in general. Free trade in this respect would act as beneficially to the one photographer as to the other, and by giving the copyright in photographs to the public—for their own private use only, of course—the whole body of the profession would be mutually benefited.

To sum up, then, in a few words what I have attempted to advocate, I would—

1. Make the photographer, with restricted powers, the proprietor of the negative.
2. Give to the sitter the copyright in the photographs for all purposes but those of gain by publication.—I am, dear sir, yours faithfully,
ALEXANDER BASSANO.
25, Old Bond Street, Nov. 10.

DEAR SIR,—The views expressed in your leading article on this subject seem to me so entirely incorrect, that I must ask to be allowed to show where I think you are wrong.

In the days of the Daguerreotype and glass positives the sitter took away with him the thing to be paid for, and only in rare cases was an extra portrait left in the photographer's hands; and in those rare cases, what happened if any use was made of the portrait without the consent of the sitter? In some instances we heard of smashed show-cases, and appeals to a magistrate. In the first instance, it seems to me that the only reason why it became a rule for the negative to remain in the custody of the photographer was on account of its liability to injury. The sitter was entitled to the possession of the negative just in the same way as he is to his name-plate, for which he has paid the engraver, and for the cards that have been printed from it. The case of the type-printer is different: we pay for impressions only, and if we want the type to be kept standing, we must pay an extra price.

The prevailing rule amongst photographers is, I think, a good one. He keeps the negative because he has convenience for doing so, and it answers his purpose in view of new orders. I do not, however, see why, in consequence of indifference, in the first instance, on the part of the sitters, he has been allowed to retain possession of the negative, he should now claim the copyright. I maintain that custom alone has given the photographer the privilege to retain the negative, and that the copyright in it belongs entirely to the sitter, who, if he choose to do so, may order any kind of copy or enlargement from it, and may do with it just as he please, and may have the prints copied in any form without consulting the photographer. I am speaking now with the experience of over twenty years; and I endorse every word of what Mr. Bassano says on the subject; namely, that if it became law that the photographer has the copyright, it will practically put a stop to business in copying and enlarging.

Most people are very hazy in their ideas as to when a photograph was taken. Let us suppose that the new law is prospective only. In the course of a few years a portrait will be presented to a photographer for enlargement, and his first question will be, "When was this taken?" Of course, there will be doubt as to whether it was before or after the passing of the Act. In numberless cases it will be found that the portrait was taken at some small seaside or country town, and the photographer may still be there, or he may not; yet it will be illegal to make the copy. But suppose the photographer and the negative to be still in existence: in how many cases would it be possible for our clients to get what they wish for (say, a five or a fifty guinea picture) at the little seaside place I have imagined? On the other hand, Mr. Bassano himself may be asked to copy one of my own portraits. By all means let him do it, or, better still, let him apply to me for a transparency. I claim no copyright, and he would please his client by producing just what is wanted.

Surely, Mr. Editor, I have said enough to show you that photographers have not a shadow of a claim to copyright in the prints from the negatives which they hold merely in trust for their clients! I have no objection to the custom of holding the negative being made legal, or that the photographer may destroy the negative if he choose to do so.

Most photographers know that their clients can seldom tell the difference between a copy and an original print, and when they do see a difference they do not know its cause. I am speaking of plain copies of about the same size as the original. There is a large amount of this sort of thing done for the sake of cheapness; and here, I think, a little law would be advisable. By all means let it be made illegal to mount such copies on cards with the name of the copyist; they should either be mounted on plain cards, or the word "copy" should be distinctly shown on the copy.

There is much to be said in favour of the photographer retaining possession of the negative: he should always have the right to print from his own negatives. I have seen the folly of allowing some amateurs to print for themselves.—Yours truly,
A. BROTHERS.

[Surely our correspondent must see that there is no force in his argument when he contradicts himself. How can the photographer have the right to print from his own negatives if the copyright belong to some one else?—ED.]

MR. GALE'S SWALLOW.

SIR,—In reply to my inquiry, we are again told by your contemporary, who is apparently angry at any reference to his connection with Liverpool, that "Mr. Gale's assurance has been given that there is no trickery" (your contemporary's word, not mine) in his picture with the swallow. This being so, it would be very interesting to photographers if Mr. Gale himself would confirm that assurance, which he has hitherto omitted to do, and at the same time, perhaps, he would enlighten us as to how he managed to make the swallow—a speck moving at certainly more than twenty miles an hour—the sharpest point in the picture! A glance will show that every other part of the photograph (which was not moving) is soft, although well defined, but the speck representing the bird is hard, sharp, and out-out in effect. If Mr. Gale has really stated that his picture is genuine, he can of course have no objection to showing the negative; it would be of enormous interest, being the first bird picture ever stated by its author to be direct from nature. If he has not said it is genuine, he has an opportunity of correcting an erroneous statement. INQUIRER.

SOCIETY BEAUTIES.

SIR,—If the eminent firms of photographers who published the greatest numbers of the famous Photographic (so-called) Beauties had informed the Press and public generally what the large quantity of positions were taken for, it would, I imagine, place photographers in a much better light than they now seem to occupy. Unless the orders given by the ladies were very large, it did not pay to take so many for them only. If they were taken, as most people would naturally suppose, for publication, why object, or instruct their husbands to object, because an absurd article held them up to ridicule? They should have consulted their husbands' wishes first. OPERATOR.

THE PRESS AND COPYRIGHT.

We extract from the *Lincoln Gazette* the following paragraph about Photographic Copyright and the Rosenberg trial. After the ignorant and puerile remarks of the London Press generally, it is refreshing to find a provincial paper able to present the case in a reasonable light.

The man with a grievance just now is the "poor photographer." He has been assailed right and left as a person without principle, who thought more of his own pocket than others' people's feelings, and who, against all remonstrance, insisted

on exhibiting and selling the portraits of the Beauties of the day. But he is not so black as he is painted. According to the latest legal lights there is no copyright in a photograph, and Lord Westbury's Act is so dubiously worded, in that fearfully lumbering style peculiar to parchment, that nobody can tell whether the picture belongs to the sitter or to the photographer, except, indeed, under special conditions, which are not carried out once in a million of times. The photographers themselves were in the dark as to their rights until Mr. Montagu Williams cleared up the matter. It now appears to be understood that if the photographer is paid for the picture the copyright rests with the purchaser. It is his by courtesy, if not by strict law. The photographer asserts that the negative is his property, but the image upon it can only be printed by order of the person who has paid. No respectable photographer would even show a specimen without permission, and far less publish copies for profit. But if a beautiful woman is invited to sit for her photograph, and consents to be taken in every kind of picturesque dress and dramatic attitude, it is an understood thing that she is willing that the picture should be public property. No private people, however lovely, are seen in shop windows, and it is only the Queens of Society who have thus figured and been classed with miscellaneous celebrities. It is understood that the Queen of these Queens, her Majesty, is much shocked at the publicity given to certain pretty faces of her Court, and that it is greatly in deference to her wishes that a stir has been made, and that the Langtreys and Wests have done their best to retire from the windows which, with their own consent, they once adorned.

"LOOKING BACK."

BY AN OPERATOR.

CHAPTER X.

HARD TIMES--A DINNER OFF GAS PIPES--THE USUAL ENDING OF THOSE QUIET LITTLE BUSINESSES.

THUS bad began, and worse remained behind. I was indefatigable in my exertions to make that miserable place pay. I never worked so hard in my life, and never was poorer. It was no use sitting down to wait for customers—waiting would not fetch the dinner; we had to catch the first before we could get the latter. I remember how concerned I was about my appetite during that awful period! I thought it enormous—I was always hungry. I used to feast off peaspudding and boiled beef bought cooked in the Essex Road like a healthy cannibal, and wash it down with four ale with a gusto that would have excited the envy of an alderman. That is one piece of knowledge that the quiet business taught me, viz., that poverty, although it makes a long face, requires but few stomach tonics, and that hunger is really the best and cheapest sauce in the market.

In spite of all [my clubs, my Sunday work, and all my efforts, things were gradually and imperceptibly getting worse. An MS. that I had sent to a paper for "perusal and approval," and on which I depended to keep me over quarter-day, miscarried—it was returned as unsuitable. The weather was foggy, wet, and dreary. People were offended when you solicited a sitting, and passed you over with the remark, "Wait until the weather gets finer!" Then, to cap all, the Doctor and the nurse had to be called in. There were fees to be paid, and I had another mouth, albeit a little one, to provide for out of this nice quiet business. Things were looking black indeed. I feel sure that some people would have gone out of their minds if they had been placed in the same position. However, thank God! I was never of a desponding turn of mind, and am possessed of the happy knack of making the most of whatever strait I've been placed in. It is comforting to know that you will not die of worry; and I am certain that will not be my final complaint, for if worry could possibly have done it, it would have finished me during the time I was owner of that "quiet business."

As sure as I managed to scrape twenty shillings together and placed them for safety in an old tin box, that we once had foolishly and foully hoped to fill at least once a week, than there was an instant demand for it—

poor rate, water rate, police rate, or gas. There were sure some of them to be due. And here let me lift up my voice and anathematise that vile, vulgar, and loud-voiced gas collector! He was the only man whose tones ever struck terror to the soul of Geo'. He was a rugged-looking fellow, and I fancy took a dislike to me from the first, for he used to look at me in a manner that made me feel as if detected in the act of committing some enormous crime. It was no use speaking gently to him while informing him that you did not find it convenient to pay. His look doubled its meaning, and you felt that the condemned cell in Newgate was too good for you. Then, when he spoke, the sound of his voice would paralyse you, for though his words were few, they were full of meaning and matter. "Yer knows it's overdue, and when next I calls, it will be—" and he finishes this unromantic speech with pantomime; he screws up his face with a wicked leer, and turns an imaginary tap with the handle of his pen.

This was the way he served me during the first two quarters; but when the third fell due things were queerer than ever, and I found it impossible to meet his demand, only a mere matter of fifteen shillings. I was awfully miserable on the night previous to the fatal day when he was to appear, and put his pantomimic threats into execution. You must acknowledge that my case was very hard, especially, as I have said before, it was only for a few shillings, and the company held a deposit from me of two pounds. I am afraid I did not say my prayers that night when I went to bed, for I, who am never troubled with restlessness in the night, was visited by some most appalling visions. Amongst the rest I dreamt that I met that gas collector out on a dark rolling ocean; my heart leaped at the sight, for I knew that I was in an element where I was superior to an hundred such as he; my joy was demoniacal! I could see him glare in his terror, and clasp in desperation his accursed account book—his sole prop that kept him from sinking. The infernal pleasure I felt at that moment is indescribable! With a yell I dashed through the waves—I tore the book from his grasp, and—and then I awakened myself with my hysterical laughter.

I lay awake during the rest of the night thinking over all the troubles that this quiet business had brought upon me. I do not recollect what my thoughts actually were; I fancy that they were rather sour and bitter—in fact, anything but pleasant, so I will allow my readers to imagine them. One thing I resolved upon, as I arose next morning, and that was, that let fortune do her worst, she could only take from me the tables and chairs; she could make no demands upon my spirit or my honesty, and these I determined I should only surrender with my life.

Those early morning thoughts did me a power of good, for when a man sets himself to think earnestly, he, as a rule, will think right; and he who thinks right must, of a necessity, see the way that truth and honesty lie, and consequently imbibe courage to face the troubles that surround him. I saw clearly the mistake that I had made—I saw the inevitable end that some day must overtake us; but, like a bold (some might say foolhardy) captain, I stuck to my coffin ship as long as one plank held on another, and then had the melancholy satisfaction of sitting on my chest, weather beaten and forlorn, and exclaiming, "I have done my duty!"

Still, and in despite of those resolutions, I could not help but feel—and feel sorely—the truth of the old saying that "It's hard for an empty bag to stand upright."

However, I felt lighter of heart that morning after my little philosophical deductions than I had done for many a day previous, and when I thought of the impending visit of the gas collector, the vague, unhappy feeling was gone, and a burning wish to be revenged on him in a quiet sort of way took its place. By the time that breakfast was over I had formed my little plan, and as eagerly waited for his appearance as what I had dreaded it before. Would

you believe it?—he did not come that day. Just the way of the world. Had I been sitting there quaking and composing pathetic speeches, imploring him to delay, the turning of it off for another week, he would have been there to the minute, and would have been as marble to my appeals. However, next day he came. I flew to meet him. A shade of disappointment crossed his sour visage as I came forward grinning; he evidently thought I was going to pay.

"Good morning! How are you? Been looking for you; I expected you yesterday!" I exclaimed in a hearty manner.

"Fifteen and nine!" he growled.

"Thank you, I know it! Now be quiet about it."

"Quick about what?" he asked.

"Quick and turn it off," I answered, grinning.

I had fairly taken the wind out of his sails. I never saw a man look so silly in my life. He opened his mouth as if he would swallow me, and dropped his book with amazement. In picking up the latter, his hat tipped off, and in following it his ink got spilled all down his light pants. He then fell a-cursing.

I then addressed him in fatherly accents.

"Friend, I beseech you, do not blaspheme; there is a law against it, and, as sure as you fall to't, I shall run you in. As a trustworthy servant of a respectable company, I am amazed to see you fooling about thus with your book and your hat. Remember that time flies! Do your work honestly by your employers, and *turn off my gas*."

He obeyed in silence, and then went to the opposite side of the street, and had a good stare. As I had paid for the fixtures, I now inspected the piping, the brackets, and gaselier, and, before dinner time, I had sold the lot for fourteen shillings. On the way home, after buying a couple of paraffin lamps to do in place of the gas, the delicious exhalations of rich frizzling sausages struck upon my olfactory organ. There was only cheese and bread at home! I couldn't resist the flesh pots, so in I went to steaming Egypt, and came forth laden with a mess that kept my mouth like a rain cloud until I got home.

"What have you got there?" asked my wife.

"Fried gas pipes," I answered, laconically.

We both burst into a hearty laugh, and sat down to as hearty a dinner as ever we sat in our lives, my better half remarking, quite sententiously, "Well, Geo', there is never any great loss, but what there is some small profit!"

In the morning I went and drew the balance of my gas deposit, and with the proceeds paid my poor-rate. But why follow up this tirade of struggles—why continue this dismal dirge? I was indeed like Poe's unfortunate raven's master—

"More unmerciful disaster

Followed fast, and followed faster."

What puzzles me now, on looking back at that awful struggle, is that I never thought of selling the things or having them removed, or doing some of the moonlight tricks that poor devils have resource to under similar circumstances. However, I didn't! I pawned my watch, I parted with my little bits of jewellery, but to have touched the furniture would have been desecration—so when the hoary-headed rascal of a landlord sent in the bailiffs, and left a dirty, greasy, lank-jawed, leer-faced man in possession, he got a good haul. I had not expected such harsh treatment from the land lord, but however, I learned afterwards that he was an unscrupulous blackguard. And, as a man of the world, let me speak this: had I sold the things and quietly departed, I must conscientiously say that it would have served the landlord right, for the villain knew perfectly, when I was on the purchasing of the business, that the place was rotten—that, in short, no mortal on earth could make a living in it! As an honest man it was his duty to let me know that Jinks was only too glad to get hold of me—that, in fact, it was as much in his pocket as in Jinks's, for he received three quarters arrears.

I blame the old landlord far more than I blame Jinks.

Jinks had been trieked, and naturally wished to get back part of his money, the same as a few tenants before him had done; but here was this old spider—this grasping elf—sitting quietly in the background aiding and abetting all these swindles, and, like another Fagin with his young prigs, licking in all the fat that their labours produced.

So now we had got to the length of our tether.

"I say, Geo'," quoth my wife, "here is the man in possession asking when we dine."

"All right, my dear, I shall go and tell him," I answered.

I found him sitting smoking a villainous smelling pipe in a back room where we did our toning and fixing. He was one of those peculiar people that you never see except on dreary occasions—people that you meet at deaths, prayer meetings, temperance halls, or other dismal and depressing places—people that you feel certain dwell in dungeons and cellars—people that bring toads and mildew and mould into your mind, and whom you term, in common parlance, wet blankets. There he sat blinking at me with his greedy, fishy eyes, and puffing at his charnel house pipe with all the complacency of a reptile who has dined.

"Friend," quoth I, in my most serious tones, "are you a vegetarian?"

He looked like as if he had lived upon slime.

"A wot?" he asked.

"Do you live upon vegetables?"

"They're very good along with a bit o' pork, Mist'r replied, as he snacked his lank jaws.

"Good," I answered; "you will have to suppl' yourself."

"Vot! Ere ye Jews?"

"Worse than that—we are Lucretia Borgians!" I replied solemnly. "We are bound to eat nothing but vegetables, and those we season highly with various poisons: thus we, this morning, breakfasted off a mess of pottage flavoured with arsenic; to dinner we have a rare broth whose principal ingredient is the sweet, yet deadly hemlock; for supper we shall have a savoury dish of toad-stools fried with virdigris."

"Oh! the bleeding martyrs!" cried he. "What a devil's den have I got into? I only wonder you do not sup off fire and brimstone. I'll be a dead man before I'm four-and-twenty hours here."

"Shall I send you down some of the broth?"

"No, thank ye—no, thank ye! The devil a pick of anything I'll have in this house but what my 'ole woman brings me!"

And then that became the cheapest and quietest man in possession ever anyone saw. He would not accept of a glass of beer or a pipe full of tobacco from me. He used to hurry away to the back premises when he observed me approaching, and used to tell my wife, when he got the chance, that he would see my "statue done in wax work at Madame Tussaud's afore long," and then add, with a grin, "and in the chamber of 'orrors, too!"

Thus the week rolled on, and at last the furniture van came to the door, and away went everything but our boxes and our clothes. On the first appearance of the van I sent my wife out of the bustle, and when it was over, and the house completely gutted, I went and fastened the windows and doors securely, saw that there was no one left in the unlucky place, and came forth. The landlord was standing on the curb-stone. I locked the door and put the key in my pocket.

"What are you going to do with that key?" asked the landlord.

"I am going to keep it."

"But I have a tenant coming to look at the premises!"

"Good! Then if you wish this key you can have it for five pounds. I know the law, and I defy you to enter those premises for six months without my consent."

I bade him good morning, and walked off. Next day I accepted an offer of fifty shillings for the key, and thus ended my connection with the "quiet little business."

THE LATE LORD MAYOR AND INDECENT PHOTOGRAPHS.

THE recent escapade of a gentleman endowed for the moment with the dignity and power attaching to the office of chief magistrate of the City of London is one of those things which everybody would willingly allow to be forgotten, hidden under the universal contempt with which it is looked upon. The office of the Lord Mayor of London is associated in ancient times with many of the liberties of the people of England; and if it were nothing else in our day, it is the representative fountain and medium of all great acts of charity and benevolence in every case of public calamity. Hence no one can exult when the pettiness of one man, whose little authority was fortunately very brief, for a moment smirched the dignity of his office. We briefly refer to the matter because the occasion seized to gratify a little personal spleen was one which has left many anxieties on the minds of photographers, who begin to ask where safety is to be found. If the issuing of photographs of one class of Her Majesty's subjects—for as such the Zulus may now, we presume, be regarded—in their every-day costume be a legitimate subject of prosecution, is it safe to photograph the liberal charms of a British matron in evening dress? A rumour has gained some credence that this was but the first step of a general raid upon photographers, who were to be prosecuted for anything which could be construed as of questionable taste or decency. A well-known high-class photographer, who has gained considerable credit for the excellence of his photographs of statuary, recently received an anonymous letter, purporting to be a friendly hint, advising him to get rid of all his photographs of statuary taken at the recent Paris Exhibition, and anything of a similar nature in his possession. It is to be regretted that the late Lord Mayor's little plan of harassing some of his colleagues has been the occasion of a panic in some quarters.

From well-founded rumours in the City it seems to be understood, however, that prosecuting photographers in the interests of decency was not the primary aim in the late case. It is understood that some of the civic authorities had personally made endeavours to repair the laches which the chief dignitary's shabbiness had occasioned in regard to the credit and hospitality of the office. Those most prominent in endeavouring to save the dignity of the civic chair, of whom Mr. Alderman Nottage was one, earned the defaulter's bitter dislike, and this prosecution was one of the modes of indirect and unstraightforward annoyance. From a letter published by the solicitor for Mr. Phillpott, we learn that this was not a police prosecution at all. It was instituted by the Lord Mayor, conducted before the Lord Mayor, and decided by the Lord Mayor, who exacted a promise from the defendant that he would not sell any more of the cards just before he dismissed the summons, admitting thereby that there was no case for prosecution at all.

We think, then, that photographers may take heart of grace, and issue, in the regular prosecution of their business, whatever their own sense of decency justifies as having no prurient or indecent intention. It has been alleged that Mr. Alderman Nottage intended to follow up the late Mayor's illegalities until they met with their just punishment. If he fail in this it will not be, we apprehend, for lack of public spirit or enterprize, but rather from the contemptuous forbearance which will leave the delinquent to the obscurity into which he will naturally fall.

DEVELOPING GELATINE PLATES IN DAY-LIGHT.

THE one drawback—and beyond question a serious one—attendant upon the use of highly sensitive gelatine plates has been found in the fact that they could not be developed—or, in fact, uncovered for any purpose—in the ordinary dark room, illuminated with sufficient yellow light to permit of comfort in working. Extreme sensitiveness to feeble radiations has inevitably brought with it the risk of fog or abnormal action of light on the surface of the plate, if light possessing any actinic power whatever should come in contact therewith. The special claim of these plates is their sensitiveness to weak light, and that they are not wholly insensible to yellow light. Hence it should not be matter of surprise or impatience that they fog if opened or developed in the light of the ordinary dark room. To secure safety, it has been found necessary not only to reduce the area through which light could pass, but also to glaze that with deep ruby glass, two thicknesses being better and safer than one. With patience and practice it is not difficult to succeed with this small amount of light. But beginners often fail in the necessary precautions, and often, in consequence, blame the plates or the process altogether, and so fail to secure for themselves one of the greatest boons the art has ever placed within their power.

Mr. Werge has changed all this, and made development of the most sensitive plates easy in an ordinary sitting room, or, at any rate, in a well-lighted dark room. Amongst the many ingenious appliances exhibited at the recent South London Technical meeting, none excited greater interest than the developing tray of Mr. Werge, in which he developed in the full gas-light of the room a gelatine plate which had been exposed in the morning, and exhibited to the meeting the result in a clean transparency, without fog, or any trace of the abnormal action of light. The matter is, of course, very simple. The plate is developed in a covered tray, and is so protected from light. The arrangement consists of an ebonite tray, fitted in a casing of tin, grooved to allow a plate of ruby glass to slide in and cover the top of the dish or tray. There is also an aperture for a funnel, through which is poured the developing solution, &c. What arrangement exists for watching the progress of development we do not know, as we have had no opportunity of examining the apparatus. This and some other matters are doubtless provided for. We can here simply record the fact, interesting to many, that the demonstration before the South London meeting was a perfect success.

FRENCH CORRESPONDENCE.

PROCEEDINGS OF THE PHOTOGRAPHIC SOCIETY OF FRANCE. THE opening meeting after the recess of the Photographic Society of France was well attended. Several papers—among them some of considerable interest—transmitted to the Society were first read, after which M. Davanne drew the attention of the meeting to the endeavours made by M. Pelgou to arrange a series of public lectures on photography, to be delivered at the Sorbonne, and informed them that those endeavours had been attended with complete success. This course of lectures has received the

necessary official sanction, and will be delivered at half-past eight o'clock in the evening, on successive Tuesdays between the 2nd December and the 20th January next. M. Davanne, who will undertake the course, has already drawn up a complete syllabus, which was read at the meeting; and he stated that he intended to bring the whole within the limits of six lectures. The announcement of the proposed arrangements was received with acclamation.

With reference to the same subject, M. Leon Vidal also seized the opportunity of informing the meeting that he had been officially appointed Professor of a course of photography, consisting of twelve lessons, at the National School of Decorative Art at Paris. This course will be given every Sunday, and will be also open to the public. Since the funds for the expenses of this course are derived from a grant administered by the State, its organization may be considered to be an official recognition of photography as a subject of public instruction. It certainly was high time that France—the cradle of our popular art—should render to photography the professional status which it already occupies in other countries, and all who are really interested in its development and progress will entertain sincere wishes in favour of its success as a subject of public instruction. The scientific faculty of Paris, and the French Government, may have been tardy in doing their duty in this respect, but there is no doubt that the Professors who have been selected will do theirs by rendering their lectures as attractive and valuable as possible.

Among the new inventions and objects of interest exhibited at the meeting, it is right that I should specially draw attention to an exceedingly simple and useful portable stand for the camera, by M. Eugene Cheron. This stand consists of legs made of steel bars, which can be folded up or extended at pleasure, and fitting into a leather case, of sufficiently small dimensions to be carried in the pocket of the tourist. It forms a necessary complement of the travelling cameras, in rendering which portable so much ingenuity has been shown. Hitherto, the legs of these cameras, notwithstanding all the improvements they have undergone in other respects, have remained cumbersome and difficult of transport. Now this very serious objection has been overcome; henceforth photographers, when on their excursions, need only carry with them three small cases, which do not occupy more room than an opera glass, to have a firm and serviceable stand, capable of supporting a camera of any size, and without the least reason to fear the slightest oscillation. M. Cheron's ingenious apparatus weighs only from 750 to 800 grammes, measures 1.60 metres in length, and when folded into its smallest compass occupies a space of less than 8 cub. cents. We shall have in this apparatus a really valuable improvement, which only requires to be known to ensure a public success.

At the same meeting M. Ch. Petit exhibited a series of typographical prints obtained by means of photographic negatives from nature; M. Balaguy, a most enthusiastic amateur, showed some negatives on gelatine with prints taken from them as specimens, and gave a detailed explanation of his method of working with gelatino-bromide emulsions. M. Asser exhibited samples of photo-lithography. M. Poitevin gave a description of a new process for taking positive prints, depending on a reaction of the iron salts; and M. Pellet showed a graduated burette of his own invention for measuring a number of drops, as well as a new alcoholometer; and he also drew attention to certain improvements that he has introduced into his cyanoferric paper.

M. Leon Vidal brought to the notice of the Society the experiments that he had made with Dr. Van Mouckhoven's new photometer. He more particularly pointed out the defects of the new instrument which present an obstacle to its successful introduction into practice in the photographic laboratory, and he demonstrated the possibility of effecting certain improvements. As at present

constructed the instrument can only be used for a single observation at a time.

Towards the close of the meeting M. Stebbing was anxious to submit to the Society a proposal which he had already made to the South London Photographic Society, for an interchange of photographs and photographic objects between this latter Society and the Photographic Society of France. Very properly, the chairman referred M. Stebbing to the Council of the Society, before whom he should have laid his project before bringing it to the notice of the meeting, according to the established rule. This seems to show that M. Stebbing had no authority for making to the South London Society a proposal of the kind indicated. It is to be hoped that this little rebuff may act as a lesson to the honourable member. He will do well, also, to remember in future the ordinary courtesies which are due to the Press, and when again referring to our journal to speak of it as the PHOTOGRAPHIC NEWS, and not slightly as "one of the English photographic papers." *A chacun son droit!* K. VERSNAEYEN.

PURIFYING AND SOFTENING WATER.*

A PROCESS for completely removing the hardness of water, and rendering it equal to distilled water in softness, has been recently patented by Mr. A. Ashby, of Grantham. The process is especially useful for manufacturing and industrial purposes, but may also be employed for removing the whole or part of the hardness from water used for drinking or domestic purposes. After the temporary hardness, which is due to the presence of bi-carbonates of lime and magnesia, and salts of iron, has been removed from the water by the addition of lime or lime water (Clark's process), by boiling, or by any other known method, the patentee adds, for the purpose of removing the permanent hardness which is due to the presence of soluble salts of lime, magnesia and iron, other than those which cause the temporary hardness, a sufficient quantity of a solution of carbonate or bicarbonate of soda or potash, or of any other soluble carbonate or bicarbonate which will decompose and effect the precipitation in an insoluble form of the substances which produce the permanent hardness, either with or without the aid of heat, which may be applied either by means of a fire, or passing steam through coils of pipe placed in the water to be softened, or by blowing steam directly into the latter. The waste or exhaust-steam from a steam engine may be employed as an economical source of heat. Or he removes the magnesia, which may wholly or partially cause the permanent hardness, by an addition of an excess of lime during the removal of the temporary hardness, whereby the water is rendered alkaline, and the magnesia is precipitated in an insoluble form, the excess of lime being subsequently removed by the addition of a sufficient quantity of carbonate, or bicarbonate of soda, or potash, or of any other soluble carbonate or bicarbonate, and when necessary by the addition of some free carbonic acid gas after the addition of the soluble carbonate, whereby any caustic alkali which may have been formed is converted into a carbonate. The patentee prefers to have a separate mixing tank, in which the solution of carbonate or bi-carbonate may be added after the lime water has been previously added to the hard water in another mixing tank, and to have the second mixing tank of larger dimensions than the first. Where there is steam or other power, stirring gear should be placed in each tank.

In the process described, the free and half combined carbonic acid gas is first removed, so that the subsequent removal of the permanent hardness is rendered both practicable and easy. The process may be used in conjunction with Clark's process, but it is preferred to use it in conjunction with the Porter-Clark process, which removes the temporary hardness from water. The patentee says that

* *English Mechanic.*

after water has been treated by this process, it is devoid of all hardness, so that it is equal to distilled water for washing and manufacturing purposes. When determining the proper proportion of soluble carbonate or bi-carbonate to be used, proceed as follows:—After a sufficient quantity of lime or lime water has been added to combine with the free and half-combined carbonic acid, or, if required, sufficient also to remove magnesia in an insoluble form, take (say) a quarter or half-litre of the water, and drop into it from a graduated glass measure (e.g., a burette divided into cubic centimetres and parts of centimetres) some solution of soluble carbonate or bicarbonate of one per cent. strength, or of any other strength that may be found to be most convenient, and preferably some of the same solution that is going to be used in the process of softening, and then raise the water to as nearly as can be the same temperature as that to which it will be subjected during the process. In order to ascertain when just a sufficient quantity of the solution has been added, the patentee uses turmeric or red litmus paper, so as to avoid having an alkaline reaction in the water, or he adds a little solution of calcic chloride to some of the water after it has been filtered into a glass vessel, when no turbidity ought to be produced in the water; or some of the filtered water is added to a few drops of a solution of mercurous nitrate or of mercurite nitrate placed in a white basin, when no change of colour ought to take place; or any other convenient chemical reaction may be employed as an indicator. If a slight degree of alkalinity in the softened water is of no consequence, so much care need not be bestowed on this point. Should it be desired to remove only a portion of the permanent hardness, a smaller quantity of the solution of the carbonate than is indicated above may be added, and the resulting hardness of the partially softened water may then be ascertained by the standard solution of soap in ordinary use. Having now determined the relative proportions of the water which is to be softened, and of the solution of carbonate or bicarbonate which must be used in order to effect the desired amount of softening, the size of the orifices of the rectangular valves or openings through which either flows into the second mixing tank must be adjusted in the like proportions. For example, if 1,000 measures (say one litre) of the water required 10 measures (say 10 cubic centimetres) of the solution of carbonate, the two orifices must have the relative areas of 1,000 and 10. This adjustment is effected by having a slide plate fitting into one or both of the rectangular openings, which is moved by a screw, so as to increase or diminish the size of the openings. A graduated scale is placed either by the side of the graduated plate or on a circular plate at the end of the screw, which is used for turning it, or in both positions combined. In this manner the relative areas of the openings can be readily and accurately adjusted; but care must be taken that the fluid issuing from each opening has as nearly as possible the same head of pressure. A float can be arranged so as to cut off the orifices in equal proportions as the mixing tank becomes filled.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

The first meeting of the session of this Society was held in the Water Colour Gallery, Pall Mall, on the evening of Tuesday, November 11th, Mr. J. GLAISHER, F.R.S., in the chair.

The minutes of a previous meeting having been read and confirmed, the following gentlemen were proposed and elected members of the Society:—Messrs. W. Gillard, E. S. Baker, W. S. Valentine, The Hon. Mrs. Holden Hambrough, Messrs. H. S. Mendelsohn, H. W. Barton, W. J. Byrne, W. Muller, Seymour Conway, A. King, G. Watmough Webster, T. Fokel, C. R. Southwell, C. King, A. Galloway, J. Thompson, E. Goole, C. Hussey.

The PRESIDENT then proceeded to distribute the medals

awarded by the jury for the best pictures in the Exhibition, adding a few complimentary and discriminative words as to the various qualities which had earned the medals. Those who were present to receive the medals in person were Mr. W. Bedford, Mrs. S. D. G. Payne, Mr. S. D. G. Payne, Mr. T. J. Dixon, Mr. Cowan, Col. Wortley, and Mr. W. Cobb. Medals were handed to the Secretary to be forwarded to Mr. Joseph Gale, Mr. R. Faulkner, Mr. A. Diston, Messrs. J. Russell and Sons, and Mr. H. Rocher, of Chicago. We subjoin a list of the medallists, with a statement of reasons for the awards.

Medals 1879.—Joseph Gale (4)—For artistic perfection—a most perfect picture. William Bedford (48)—For the pictorial excellence of his series of landscapes, but more particularly No. 48. Mrs. S. G. Payne (108)—For the artistic arrangement and photographic excellence. T. J. Dixon (111)—For the wonderful perfection in portraying a difficult subject. S. G. Payne (125 and 67 to 71)—For high general excellence. Robert Faulkner (113 and 114)—For high artistic excellence. Hills and Saunders (128)—For very perfect artistic treatment in portraiture. Col. H. Stuart Wortley (202)—For the perfection of his instantaneous pictures. James Russell and Sons (229)—For artistic combination. A. Diston (286)—For artistic excellence. W. Cobb (338 and 339)—For artistic ability in portraiture. H. Rocher (187)—For artistic arrangement and photographic excellence.

The PRESIDENT said that when the jurors had completed their work, having examined every picture exhibited, and examined their notes, they found they had noted a very large number as meritorious, a greater number than they could with propriety distinguish by medals. Going into a careful analysis, they found that there were twelve names in regard to the merit of which they were quite unanimous; it was resolved, therefore, that these should have medals. Then there were several more in relation to which they were nearly unanimous, and it was thought desirable to specially mention them with honour; not with any intention of giving a second-rate award of "honourable mention," but a mention with honour as possessing high merit worthy of recognition. These were Messrs. Vernon Hoath, B. King, Valentine and Sons, W. J. Grant, H. Dixon, A. Clout, C. Rosetti, H. P. Robinson, A. Pringle, Dr. Huggins, F.R.S., H. S. Mendelsohn, A. Fisk, W. Willis, Jun., F. G. Norton, Nitiken, and Brandel. The Exhibition, he might add, had been a very satisfactory one. Already 3,571 persons had visited it, and as it was now resolved to keep it open until Saturday, it might be hoped the number would reach 4,000.

Mr. WARNERKE then proceeded to read a paper on Actinometers, but having read the introduction he said he thought the remainder would be better adjourned until the next meeting; in which he was confirmed by the President, who wished the meeting to resolve itself into an informal conversazione, as being pleasant on such an occasion.

This was done, and the proceedings so terminated.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The annual technical meeting in connection with this Society was held on the evening of Thursday, November 6th, in the entire room of the Society of Arts, the Rev. F. F. STATHAM in the chair.

After a few preliminary remarks by the Chairman,

Mr. WARNERKE exhibited Mons. Vidal's portable camera, and described it as follows:—

This camera was shown by Mr. Vidal at one of the Photographic Society's meetings in Paris. In conformity with the wish expressed by our president, I went to Mr. Vidal during my recent visit to Paris, who, with extreme courtesy, lent me his apparatus with special view to show it to this meeting and give explanation of its working. The principal characteristic of this camera is that there is no ground glass to focus; focusing is done by means of a small telescope, permanently attached to the back of the camera in this telescope; it is the only centre of the image that can be seen, about $\frac{1}{2}$ of an inch in diameter. But in order to direct the camera so that the idea may be formed of the position of the object to be photographed on the plate, there is a segment in brass with divisions, and a rule with two projecting knobs revolving round a pin situated in the centre of the segment are fixed, one horizontally, another vertically. Knowing the angle embraced by the lens used, the rule properly placed will readily indicate the amount of the subject to be enclosed on the plate. Mr. Vidal, however, had, during his voyage, used also a ground glass when artistic consideration required it. The sensitive plates (twenty in number) are situated in the box on the top of the camera, and travelling by

means of a rack-and-pinion. Plates are put, by a very simple contrivance, in the camera, after it is focussed; and after the exposure it is transferred back to the plate-box, by obtaining the camera with the box; but this is done by a very ingenious arrangement, not requiring the negative to be taken from the stand. There happened that in the plate-box were some negatives taken by Mr. Vidal during his last voyage to Spain. I take the liberty to show you a few of these negatives, because they will testify better than my words the value of the apparatus, and especially the perfection of focussing.

Mr. WARNERKE also exhibited an ingenious tripod stand with following top, and made the following remarks:—

A peculiar and quite novel fixture of this stand is its head, which is not a separate apparatus. Awkward generally in packing for travelling, but formed from three separate blocks of wood, hinged to the stand legs, and ingeniously jointed and screwed together, when the stand is to be made ready. The double screw of the original design fastens the head of the stand, and also fixes the camera to the stand. The enclosed diagrams will complete this description.

Mr. WARNERKE also exhibited a bottle for holding liquids which would be easily injured by contact with the atmosphere, and said:—

This bottle I constructed with a special view to keep ferrous oxalate developer for a long time. This developer, when kept in the ordinary manner, is soon decomposed by the action of air, which is readily detected by its action as developer, being after a time slower and slower, and ceases altogether, sides of the bottle being at the same time covered with insoluble iron oxide of a brown colour. Into my new bottle I put some paraffin, or any other liquid lighter than water insoluble in it, and not acting on developer. Paraffin will rise to the surface, and protect the developer from any contact with air. To draw the ferrous oxalate, when wanted, I have in the lower part of the bottle a glass tube fixed, which, when inclined, will enable me to draw any quantity of it. The bottle and developer I show was pre-

pared on the 16th of August, and it is just as active as when fresh. A portion of the developer that was used can be put back in the bottle if not preferred. Keep another similar bottle for second-hand developer, and to facilitate that I have a funnel inserted in the neck. Ordinary lamp paraffin is so little volatile that it can be kept almost open. One remark respecting the formula of oxalate developer:—

a.—Neutral oxalate of potash	100
Water... ..	250
Citric acid (when necessary)	10

to boiling solution (a.)

Oxalate of iron added	40
Water	750

If oxalate of potash is strictly neutral, the developer is immediately ready for use, and acts very clean; but I found that very often commercial oxalate of potash is alkaline. Developers prepared in that condition give foggy and flat images. Experiments often repeated demonstrate that also correction can be made with addition of potassium bromide, oxalate, tartaric, or citric acids, but this last is far better than others. It is remarkable, also, that no amount of that acid can destroy the developing power of ferrous oxalate.

Mr. WARNERKE also showed a dark slide by Jonto, of Paris, and said:—

While lightness and portability recommend this slide from the first immunity from the effect of damp, and double hinges to the shutter permitting to put it out of the wind, it will confirm good opinion in the course of working.

Mr. WARNERKE also showed a transparency which could be seen in the dark, being mounted on a plate prepared with a phosphorescent substance—sulphide of calcium.

Mr. HUGUES, who assisted in the demonstrations, called attention to a camera stand which had been sent for exhibition, very similar in its tripod head to that of the Professor from Moscow.

Mr. W. BROOKS demonstrated Mr. Willis's platinum process, developing several fine prints before the audience. He also exhibited an example of the application of the process to the production of photographs on textile fabrics.

Mr. Brooks also exhibited Mr. Cadett's pneumatic shutter for use inside the camera. He also exhibited the various con-

venient movements, combined with steadiness and simplicity, of Emerson's head-rest.

Mr. ACKLAND exhibited a mode by which the common sliding rule could be made available to indicate the exposures required with lenses of different foci and apertures.

A demonstration of the working of the Luxograph apparatus was given by Mr. ARCHER CLARKE, and some examples of the work shown.

A heating apparatus, entitled Gillingham's Radiating Hot Dresser, was exhibited.

Mr. COWAN showed a plan of calculating exposures which he had devised. He showed a method of producing a portrait negative, with vignettes and border in the camera at one operation. He also showed several mechanical contrivances for facilitating work in the studio.

Mr. WERGE showed a drop shutter, in which the rapidity of the exposure could be regulated. He also showed a method of developing extra sensitive plates in an ordinary light (see a leader).

Improved shutters were shown by Mr. WARNERKE and Mr. B. J. EDWARDS.

Mr. BAYNHAM JONES showed a camera with a little contrivance to close the opening as soon as the shutter of the dark slide was withdrawn.

Mr. F. YORK showed some contrivances of Mr. Hatch for exhibiting slides of different sizes, each duly centred, in the magic lantern.

Mr. HENDERSON exhibited a burnisher which he had had in use for some years, which had several improvements not present in those commonly in use.

Mr. BOLTON showed the Wigham burner as used by Mr. Laws for obtaining portraits by gas-light.

Mr. W. M. AYRES exhibited a safety dipper for preventing plates slipping off in the bath. Also an ingenious holder to receive negatives of different sizes for use in the copying camera. Also a dark slide for holding plates of various sizes in any part of the slide. Also a waterproof dish made from a cardboard box coated with a varnish made by dissolving gutta-percha and pitch in camphine.

Mr. FOXLEE showed a specimen of carbon printing to illustrate the effect of moisture in the "continuing" action of light.

Another tripod camera was shown, in which each leg divided and expanded like a pair of scissors, the aim being to secure increased steadiness.

Mr. J. A. HARRISON showed an improved camera front.

Some examples of Dallastype were also handed round.

The annual dinner of the Society for the following Saturday was announced, as was also a meeting of the Photographic Club on the Friday (see in our next). After some conversation the proceedings terminated.

SOUTH LONDON DINNER.

THE annual dinner of the members of the South London Photographic Society was held at the Cafe Royal, Regent Street, on the evening of Saturday last, the Rev. F. F. STATHAM, M.A., in the chair.

After a pleasant dinner, the meeting devoted itself to conviviality, in the shape of toasts and songs. After drinking "The Queen," and singing the National Anthem, the Chairman proposed "The South London Society," which was acknowledged by Mr. H. G. Cocking, the Secretary. "Amateur and Scientific Photography" were proposed by Mr. Jabez Hughes, and acknowledged by Mr. Ackland. Mr. Mawdsley proposed "Professional Photography," which Mr. Foxlee responded for. Mr. Cutehey proposed "Artistic Photography," and the response was by Mr. Payne Jennings. The Chairman proposed "Photography Abroad," which was acknowledged by Mr. Warnerke. The "Photographic Press" was proposed by Mr. Cocking, and acknowledged by Mr. Bolton. The Chairman proposed the "Vice-Chair," for which Mr. Hughes and Mr. Mawdsley responded, the former proposing the "Chair," which was duly acknowledged.

A print in platinotype of one of the groups taken at the President's house in summer was presented to Mr. Statham. Various songs and recitations by Messrs Bridge, Cobb, Heaviside, Jennings, Cocking, and the Chairman, added to the pleasures of the evening.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting was held at the Museum, Queen's Road, on Wednesday, 5th November, Lieutenant LYSAGET in the chair.

The minutes having been confirmed,

The Hon. SECRETARY stated that notice had been given of the ballot for Mr. H. N. White, of Isle of Wight; and Mr. Walter Stephens, of Bristol. These gentlemen were then unanimously elected ordinary members.

Mr. H. A. H. DANIEL desired to remind the meeting that at the previous meeting it was decided that a large international photographic exhibition be held in Bristol in the end of 1880, presuming that the guarantee fund could be raised. He was very pleased to state that the fund had been raised, and, therefore, the whole question, which was a very important one, would occupy the attention of the meeting forthwith, in accordance with the agenda paper. The whole question was then gone into, and the date of opening, design of medals, number of classes for exhibitors, and other matters connected therewith fully discussed. Time, however, did not admit of the question being entirely decided, so that the meeting was adjourned till the following Monday at the Hon. Secretary's residence.

On Monday, the 9th instant, the adjourned meeting took place at the residence of the Secretary, St. Ann's Square, for discussion. After a large amount of most careful discussion and thought, the following arrangements were finally decided upon, and embodied in circular:—

Bristol and West of England Amateur Photographic Association International Exhibition. The Council of the above Association beg to announce that they intend to hold an Exhibition of photographs, photographic apparatus, and appliances in the galleries of the Academy of Arts, Queen's Road, Clifton, Bristol. To be opened on Friday, 17th December, 1880, continuing open till Friday, 15th January, 1881.

Apart from photographs for competition, the Council will esteem it a favour if those who have any interesting examples of the history and progress of photography will kindly lend them for exhibition.

The following is a list of the medals which will be awarded for the best and second best pictures in the various classes, and to be decided on the opinions of five gentlemen—being two eminent artists and three well-known photographers, three of the judges being outside the Association.

1. A Gold Medal for the picture or series of pictures which in the opinion of the judges possesses the highest degree of merit, irrespective of size or subject.
2. One Silver and one Bronze Medal for the best and second best landscape or series of landscapes of 8½ by 6½ or under.
3. One Silver and one Bronze Medal for the best and second best landscape or series of landscapes above 8½ by 6½.
4. One Silver and one Bronze Medal for the best and second best portraits or series of portraits of 8½ by 6½ or under.
5. One Silver and one Bronze Medal for the best and second best portrait or series of portraits above 8½ by 6½.
6. One Silver and one Bronze Medal for the best and second best genre picture.
7. One Silver Medal for the best enlargement of any subject, and by any process, provided it be the work of the exhibitor.
8. One Bronze Medal for the best transparency, or series of transparencies.
9. Four Bronze Medals to be awarded according to the discretion of the judges, for improved apparatus, materials, processes, or other meritorious productions.

All communications must be addressed to the Honorary Secretary, H. A. H. Daniel, Avonmead, Leigh Road, Clifton, Bristol.

Copies of Conditions and Application Forms for intending exhibitors will shortly be forwarded to recipients of this notice, and may also be obtained on application to the Honorary Secretary.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

ON Friday evening last the Exhibition of the Photographic Society of Great Britain was open for the benefit of the Benevolent Association. With a charge of sixpence for admission

the attendance was very good, about two hundred persons being present, the fair sex being well represented. The Gallery was brilliantly lighted, and great interest in the display was manifested by the visitors, many of whom made a careful and critical survey of the pictures.

It may be mentioned that the Photographers' Benevolent Association was established to relieve any of its members, their wives, or children, who might have the misfortune to require assistance through sickness, death, or want of employment. A considerable amount of money has already been devoted to this object, and the Association contemplate forming an Invested Fund, in order to grant pensions to aged members, their widows, and orphans; but before that project can be realized, the Association must receive the support of photographers generally throughout the kingdom. If this assistance were received, the P.B.A. would become a flourishing institution; and it cannot be denied that the profession can well afford to have a charitable organization more worthy its widespread and increasing importance.

The offices are at 160A, Aldersgate Street, where the Secretary would be pleased to receive subscriptions or donations that any sympathizers may feel disposed to offer, and to enrol members.

PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.

At the last meeting, with the President, Mr. H. J. NEWTON, in the chair, after the minutes of preceding meeting had been read and approved, the Secretary announced the death of the associate member of the Institute, Dr. J. V. C. SMITH, who had long and satisfactorily filled the position of chairman of the Polytechnic Section. The encomiums on the deceased by the Secretary were endorsed and supplemented by Mr. HUDSON and Professor SEELEY, and resolutions were entered on the minutes recording the sorrow of the American Institute and of the Farmers' Club at the loss of one so eminent in his profession, so distinguished as an author, so kind and courteous in his manner, and so ready at all times to combine instruction with entertainment by drawing upon the vast fund of practical knowledge he had acquired during a life of more than fourscore years.

Mr. MASON then exhibited to the Section some prints from negatives or dry plates known as Newton's emulsion plates, and said: Some of these were made during a severe rain storm in the middle of the afternoon of Monday, August 25th. I exposed three plates which I can name, the two of the old well, and the one of the gentleman sitting in the porch of the house. I was obliged to hold an umbrella over myself and the camera to prevent getting drenched, and was surprised to get as good plates as I did. I observed a somewhat peculiar and, to me, strong effect of light this summer while on a visit to the Sterling Mountains, in the vicinity of the iron mines. On account of the necessity of roasting the iron ore to burn out the sulphur, the air in the vicinity of the furnaces is so impregnated with the sulphur vapour that it affects the light very materially. I also observed in the mountain regions that where almost the entire surface is covered with a second growth of dense foliage, very green, the light seemed to be absorbed by the foliage, and the atmosphere contained a great deal less actinism, photographically speaking, than in a district where much of the ground was cleared, and the light reflected from surrounding objects. In consequence of this I gave some of my plates sixty seconds, which was too short an exposure. After a three days' rain storm I visited the summits of two mountains, and exposed plates. I gave them from ten to twenty seconds, and all had too much exposure; five or six seconds would have been ample time. The atmosphere was very clear, having been washed for those three days. I was obliged to be very careful in developing to use a great deal of bromide to restrain the action of the developer. My experience with the plates, as far as I used them, was that they were as sensitive as wet bath plates. In this connection I have brought a little lantern which I use in developing; it weighs one ounce and a-half, is made of mica, two thicknesses, flooded with a solution of aniline in collodion, put together the collodion surfaces inside, after it is dried. The mica is moulded in four flaps or sides, hinged with cloth; it is very light and portable, and can be transported without danger of breaking. Before we adjourn I would like to ask if there is a gentleman present who is conversant with any instrument—which might be termed an actinometer—for the measurement of light during exposure in the camera, that can be used successfully with any

of our ordinary methods of landscape work. Such an instrument would be very useful in the field.

Mr. NEWTON: It is really something that is needed very much, as can be seen by Mr. Mason's experience in the country—exposing plates a minute, and not having them over-exposed, and another time exposing them in the same light (to a casual observer), and yet not requiring more than one-tenth of the time. An amateur would not be very likely to succeed in making a picture unless he had something to guide him in the time of exposure; a person accustomed to working out of doors becomes familiar with the illuminations on the ground glass, so that he can usually judge of the strength of light very accurately. Now in different parts of the country at all times of the year there is that same latitude existing, as I can testify. At Niagara Falls the time of exposure is not more than one-sixth or one-eighth of what is necessary in the Central Park in this city. Mr. Roche, I presume, can testify to that.

—Messrs. ROCHE and DUCHOCHOIS each assented to this statement as corroboration of their own experience in the field.

Mr. TAYLOR: What do you consider the standard of sensitiveness necessary in an actinometer to render it useful for field work?

Mr. MASON: One that would enable you to judge of one second exposure, or ranging from one second to two or three minutes.

Mr. TAYLOR: I shall exhibit such an instrument to the next meeting. I believe it to be the most perfect actinometer that exists. It is the invention of Mr. H. J. BURTON, of London.

Professor SEELEY suggested that there is a practical difficulty with any actinometer, invented or to be invented, which may make the use of one impracticable, viz., it measures the light which strikes it, which is a very different thing from the light which strikes the object to be photographed. He would make a practical suggestion as to actinometers. Take a piece of ordinary sensitive paper, and expose it to the direct sun rays, the sky, and then have a little book which should have printed in it the various tints in the order of strength of light, and that, after exposing the little slips of paper, you could compare with the book. I don't suppose that suggestion is new; but it strikes me, it is a proper direction of thinking. Those instruments you see described in books I don't think would be practicable at all. If Mr. Taylor has a small instrument, such as he describes, it must be something beyond anything I ever heard of.

Mr. MASON: One of Professor Seeley's points I have often considered—that is, that the instrument to be effectual should receive and be acted upon by the very light that is to make the picture; that is, the instrument should not be turned to the sky, but so that it receives its light from the view you are about to take. In fact, it should be placed inside the camera, or some similar arrangement, and receive the light through the lens as the sensitive plate receives it.

Talk in the Studio.

—PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The Exhibition will remain open on Friday and Saturday next, November 14th and 15th. It will also be opened on the evening of Saturday, at 7 p.m., and will finally close at 10 p.m.

Mr. F. A. BRIDGE AT BRUNSWICK HOUSE.—It will interest many of our readers to learn what the *South London Press* says of the esteemed treasurer of the South London Society. On Monday evening this popular entertainer gave his new monologue entertainment, entitled "Trifles," at the Railway Institution, Brunswick House, Vanxhall, assisted at the piano by Mrs. Elizabeth Stirling. Mr. Bridge's place as a monologist and entertainer is, as many of our readers know, well up in the first flight of those whose aim is to amuse those audiences familiar to institution frequenters. In the role of a snapper-up of unconsidered trifles he thoroughly sustained his reputation, and those present heartily enjoyed the anecdotes (many of them, however, somewhat ancient guests) with which the monologue is interspersed. It was also interpolated with a number of songs, which were by no means the least enjoyable feature of the entertainment.

CETEWAYO.—Mr. F. York is good enough to call our attention to the fact that Mr. Bruton, of Cape Town, had taken some portraits of the Zulu Chief which had been sent to England for publication, so that our statement to the effect that those taken by Messrs. Crews and Van Lawu were the last which would be taken was incorrect.

NEW PHOTO PRINTING PROCESS.—A new method by Herr Schahl is to coat a thin zinc plate with chromated gelatine, which he then exposes under a negative. The film is then rolled up with some reducing substance, which adheres only to the parts affected by the light. Tracing paper impregnated with iron is then pressed against the plate, and the iron being reduced at those places, an image is obtained, which is said to be much more delicate than one produced by ordinary photolithography.—*Scientific American.*

LIGHT AND WARMTH.—Professor Rood divides the spectrum of white light into 12 parts, and multiplies the space occupied by each part by the relative luminous intensity. In that way he obtains the following numbers: Red, 54; orange red, 140; pure orange, 80; orange yellow, 114; yellow, 54; greenish yellow, 206; yellowish green, 121; green and greenish blue, 134; prussian blue, 32; blue, 40; violet approaching to ultramarine, 20; pure violet, 5. The quantity of light in the "warm" colours is thus three times greater than that in the "cold" colours.

PREPARATION OF ALBUMENIZED PAPER.—The *Scientific American* says:—"Leicester supplies very large quantities, and many of the largest firms in the kingdom are supplied by Messrs. Meadows and Son. No less than 5,000 eggs passed through the hands of those engaged, the whites only being utilized; and the enormous number of yolks are more than sufficient to supply Messrs. Dent's manufactory at Worcester, the yolks being in great demand for glove purposes. There is a demand for the yolks in Leicester for confectionery purposes; but the supply is more than being consumed, many being thrown away daily. Every sheet has to be bathed singly, and each pressed before the ream is allowed to pass out of the hands of the manufacturers. There are all kinds of tints; and the senior member of the firm being a practical chemist, and one of the best known among the members of the Pharmaceutical Society, brings his scientific knowledge to bear. It may not be uninteresting to know that a first-class hand—females only being employed, owing to their tender manipulation—can earn as much as thirty-six shillings a week; many can earn twenty shillings, and even half-timers can receive weekly as much as eight shillings, and this without having the disadvantage of being in badly-ventilated premises.

To Correspondents.

THE YEAR-BOOK OF PHOTOGRAPHY, 1880. In order to facilitate our labours in preparing the YEAR-BOOK OF PHOTOGRAPHY for next year, we shall be greatly obliged to those of our readers who can favour us with brief practical papers on subjects arising in their experience, so that our annual may be, as it is designed, a complete record of the progress of the year, and a trustworthy practical guide for the future.

* * * **"LOOKING BACK."** THE RETOUCHING MEDIUM.—To several correspondents who have sent stamped envelopes, we have sent information regarding the retouching medium recommended in "Looking Back" a few weeks ago. Several applicants have written without observing the condition of sending a stamped and addressed envelope, and one, when reminded of the omission, politely replied that he was quite positive that he had sent a stamp. As we see no impropriety under the circumstances in making public the name of the firm supplying the retouching medium, we will avoid further trouble to our correspondents and ourselves by mentioning here that it is the retouching medium of the Autotype Company to which our contributor refers in "Looking Back."

G. N.—To secure a rich purple black tone, you must have a good brilliant negative, and print deep. With a weak negative it is impossible to secure rich, deep-toned prints.

A SUBSCRIBER.—The probable cause for the faint light-coloured lines in the direction of the dip is floating scum on the surface of the silver solution. Take a few strips of clean blotting-paper and draw them over the surface of the solution in the bath, until you remove all trace of a greasy metallic looking scum, and then proceed to try the bath with a plate, and if it is still unsatisfactory let us know the result. We regret that we have not time to answer photographic questions by post.

SMITH AND SON.—Any article made of pure silver ought to have the "hall mark," which consists of a series of small designs which alter every year. If you require a proper assay to ascertain the quality of the silver, you must send it to a refiner. If you are anxious to test it yourself, take a piece of the metal, and dissolve it in nitric acid. When all is dissolved, add hydrochloric acid to precipitate the silver, which will fall as a white chloride, the alloy (probably copper) remaining in solution, which will be green.

A CONSTANT READER.—The position and design of your projected studio will do very well if you have an uninterrupted light. Of course you intend to carry the side light to within two feet or so of the ground. We see no advantage in taking in the side light towards the centre as in design No. 2. We should prefer it kept straight.

STEPHEN PERRY.—The common defect of collodion prints is the grey slaty tone. The best mode of avoiding this is to work in a good light, giving full exposure and quick development. Pyrogallol acid should be used for development; say, pyro, 2 grains; acetic acid, 30 minims; water, 1 ounce. Tone with a neutral solution of chloride of gold one grain to an ounce of water. This will give you rich black or purple black tones.

F. C. K.—We do not know anything of the lens you mention nor can we offer a guess. The diameter of a lens affords no indication of the size it will cover; that is decided by its focus and aperture. We do not remember the name you mention as an optician or maker of lenses.

ANXIOUS.—You will see on a moment's reflection how impossible it would be for us to attempt to answer your question as to which of the commercial samples of rapid gelatine plates. It would be very unfair to publish an opinion if we could do so. But even if it would be fair, it would require a most carefully conducted and exhaustive series of experiments to arrive at a conclusion. We can simply say we have heard good reports of all of them at times.

B. D.—As a rule, a good negative, taken with good chemicals and good light, does not require much intensification, but comes right with the single operation of developing.

H. NACH.—The publication called *Light* is a weekly journal published in Fleet Street, No. 40, we believe; it can be obtained through any news agent or bookseller. We do not know of any place where you can buy French weights and measures in town; but your stock dealer will doubtless be able to get such things for you.

J. G.—For a beginner in portraiture we should recommend a card lens and camera, and one for whole plate or 10 by 8 plates.

Further notice of the Photographic Exhibition, and several articles in type, are compelled to stand over for lack of space.

PHOTOGRAPHIC CLUB.—Report of preliminary proceedings in our next.

Several correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

STEEL FOR CAMERA STANDS—LECTURES ON PHOTOGRAPHY—SUMMER-TIME AND PHOTOGRAPHY.

Steel for Camera Stands.—We see that steel—which has lately been introduced for construction purposes for all sorts of purposes—from lady's dress-holders to ponderous battle-ships—has now been adopted for camera stands. M. Eugene Cheron recently exhibited to the French Photographic Society, it seems, a steel camera-stand weighing but some seven hundred and fifty to eight hundred grammes, and fitting into a small leather case that could be carried in a tourist's pocket. We are glad that this strong and flexible metal has thus been made use of, and in connection with an apparatus where it should be found very useful. Our Paris Correspondent last week gives a short account of M. Cheron's stand, and that is all the information we possess on the subject; but we can very well understand that if the qualities of steel are properly made use of, the result would be a stand of considerable value. We are told that with it there is no fear of the slightest oscillation; and if this is really the case, the innovation is great indeed. In the case of small camera stands, light and portable, such as are usually employed by travellers and tourists, the one serious drawback is oscillation. We have seen the most charming little cameras made for travellers, fitted with every convenient detail, and resembling a piece of jewelry, so deftly and perfectly were they put together. But the skill and workmanship spent on their construction has been rendered vain by reason of the impossibility of keeping them steady out of doors. There is no need for a wind to shake the Z-phyr apparatus. The softest breath of air is enough to make the tiny apparatus tremble, set up on its slender tripod. Protect how you will by tree, trunk, wall, or umbrella, you can see your instrument perceptibly shaking, and the result is that when you get home and develop your pictures, one-half of them are found to be fuzzy and unsharp. Anything, therefore, that will give us a light and portable stand, which at the same time may be relied upon for steadiness, must be regarded with favour, and we cannot help thinking that in steel may be found the desideratum for which we have been looking and longing. By making good use of the elasticity of steel, and employing it to form a steady frame-work for a stand, there should be no difficulty in securing a stout and stable structure, which, when taken to pieces, need consist of but a few light bows and rods of metal. There are many ways, no doubt, of rendering the slender wooden tripod that a tourist usually employs more steady by employing a few tent-pegs and lines, or the rougher expedient of a weighty stone; but all these contrivances add to the difficulty of getting pictures, and are never satisfactory, from the fact that they really add to the weight and impediments which the photographer must carry. In our time we have had some experience of camera-stands in travelling, and therefore speak upon the subject with some sympathy. We have tried the simple Alpen-stock, which splits into three, and is then made to support the camera. We have used the expedient of bracing three walking-sticks together, adapted to the purpose before starting; we have employed a sort of umbrella-stick, pegged down to the ground on all sides, and we have always found that rigidity and steadiness increased only in the ratio of the weight of the stand. It, therefore, we wanted a firm stand, it was necessary to carry plenty of weight. With the use of steel, however, we hope the much-vaunted difficulty will be overcome, and before long our makers in London will no doubt follow suit of those in Paris, and furnish us with firm and portable stands made from this material.

Lectures on Photography.—It seems that the French capital is following the example of Brussels and Vienna, and in-

stituting a series of public lectures on photography. How long will it be, we wonder, before such a step is taken London? M. Davanne, we are informed, than whom a more capable man could not be found, is engaged to deliver at the Sorbonne a series of six lectures on photography at the expense of the State, while M. Leon Vidal, whose name is well known to the readers of this journal, has, it seems, been officially appointed professor of a course of photography at the National School of Decorative Art in Paris. In his case, also, the lectures will be public, the expenses being derived from a grant administered by the State. So that we have here two courses of lectures to be delivered in Paris on photography, where those who desire to occupy themselves with the art may learn something. In this country, science and art are left pretty much to look after themselves, and if we waited for a spontaneous grant from Government to supply courses of practical lectures of this kind, we should have to wait long. It is necessary, therefore, to turn elsewhere for such aid, and we cannot help thinking that the Photographic Society might help with advantage. It is notorious that both on the subjects of chemistry and optics our photographers, as a rule, are deficient; even those in the foremost rank might be better informed in the matter of reactions and the laws of light, and thus a really good course of lectures on these subjects should be welcome with us. There are few photo-chemists, probably, capable of giving such a series of lectures as practical photographers desire, but nevertheless they are to be found, if the council of the Photographic Society desired to make the experiment. There would be little use in having the ordinary professor of chemistry to lecture to photographers, since it is not the general outline of that science, but chemistry in special relation to photography, that is desired; and, strange as it may seem, there are a very large number of chemists who are perfectly innocent of photographic practice and processes. In respect to optics, again, it would be necessary to enlist someone into the service who is familiar with the construction of photographic lenses in particular, and not a physicist who has paid the subject no special attention. It is but a few years since that Professor Stokes, the well-known secretary to the Royal Society, gave a most interesting lecture at one of the meetings of the Photographic Society, and showed how very deficient most of us were in the laws of optics that govern our every-day work. On that occasion, we remember, Professor Stokes spoke enthusiastically of the services rendered to photographers by Mr. J. H. Dallmeyer, and this leads us to suggest that if at any time the idea we have just put forward about lectures should ever come to be entertained, Mr. Dallmeyer would be one of those able and competent to treat on the subject of optics before photographers.

Summer-time and Photography.—We have just received a very complimentary letter of thanks from a gentleman to whom we had forwarded a ticket of admission to the Photographic Exhibition. The gentleman in question is a journalist, and moreover an art-critic. He says nothing one way or another about the art aspect of the pictures he saw, but he is enthusiastic upon the subject of having spent an hour on a cold inhospitable day among reminiscences of summer time. It was like strolling up a country lane, he says, to stand opposite some of Mr. Bedford's pictures, while a delicate study of foliage by Payne Jennings caused him to cross and recross the room several times, so that he might feast enough upon the summer scene. We know a gentleman who likes to have *Punch* bound, so that in the hot summer days he may refresh himself with a sight of skating and snow-ball pictures, while in winter he can recall what summer is like by a glance at some of the sunny sea-side sketches to be found in the London Charivari. Our friend at the Exhibition looked at the pictures as evidence that we have summer-time sometimes, and certainly this is a very good way of enjoying good photographs.

THE MISHAPS OF A PHOTOGRAPHIC TOUR.

BY JOHN URIE.*

THE true artist or poet, whose province is to depict the beautiful, cannot have too much of the invigorating stimulus supplied by pursuits on mountain or by flood. The varied phases of the landscape are all suggestive—in towering grandeur or softened outline; and, whether Nature frown or smile, the varying scenes have golden stores for him. But it is on the expansive loch or spreading river, with their rugged or mountainous shores, when your true artist is watching the nimble movements of the finny tribes below which he is bent on capturing, and the passing light and shadows are adding to the charm of the scene, that he realises the close intimacy between art and natural phenomena. With these feelings uppermost, and having arranged with a party of fishing friends to take a tour along the Callander and Oban Railway, I thought I might "kill two birds with one stone" by combining photography with the gentle art of angling.

We left the Caledonian station about seven a.m., passing through Stirling, with its historical castle towering above the town, and casting its shadow over many scenes memorable in Scottish history, with the Wallace Monument in the distance. The Abbey Craig is in sight, and now we are at the Bridge of Allon, celebrated for its mineral wells. Here the artist will be well repaid for lingering for a few days, as many excellent photographs might be taken of the notable scenery around. Dunblane is then reached, with its venerable cathedral, affording many attractive adjuncts for a telling sketch. But we are now running along the beautiful banks of Allan Water, full of pictorial subjects for the camera, and anon are passing the old-fashioned town of Doune, and have a glance at the ruins of Doune Castle, while near at hand is Bracklin falls and the old Roman Camp. Further on is Callander—a beautiful and fashionable resort, and, from its central position, affording many facilities for sketching and photographing. A few miles from hence are the celebrated Trosachs and Loch Katrine, immortalised by Sir Walter Scott in his poetic descriptions in the *Lady of the Lake*.

In leaving Callander we keep close to the river Lenny, and get a view of the celebrated Pass of Lenny, one of the gates to the Highlands, and where a few resolute men might keep a whole army at bay. Here the river foams and tumbles over large masses of rugged rock, forming many effective cascades quite enticing to the photographer in quest of the beautiful; and, I believe, that with rapid dry plates the motion of the falling water might almost be caught.

Now we are running along Loch Lubnaig, where may be seen the graceful swan gliding along its surface in queenlike majesty, and the solitary heron standing in its waters as if asleep, but ever ready to pounce on any unsuspecting fish that may come in his way. The artist's attention is here arrested by the glorious view before him. Rugged, towering mountains and scraggy woods—deep, dark pools and raging waterfalls—combine to make one grand picture, which, like the kaleidoscope, is ever-changing, as you change your point of view, as the shadows on the mighty hills flit from mountain to mountain, or the mist rises or falls, and send their shadows on the calm, narrow lake below, as it winds for five miles through scenery at once picturesque and romantic. We travel through the country of Rob Roy, rendered famous by the daring deeds and raids of the dauntless freebooter, and where repose his remains. We pass on to Loch Earn Head, whose waters lie far below, with Ben Varloch in the distance, as if guardian of the lovely scene. On we go to Killen, the station for Loch Tay, and then enter Glenogle, or the Kyber Pass, and where at every step nature may be seen in every variety of wild and terrific grandeur. The hills look as if torn asunder, leaving the huge, loose fragments of bare rock hanging on the hill side, as if threatening all below with instant destruction.

* Read before the Glasgow Photographic Association.

The train runs along the face of the hill built, as it were, on these fragments of rocks referred to above, and the precipice beneath is awfully grand on the traveller looking down. In the distance runs the wild and picturesque river, the Dochart, with its dark pools, foaming falls, and rugged rapids, made famous by the pictures of Docherty and other artists. We now pass along the shore of Loch Dochart—altogether a lovely loch, or, rather, two swellings in the river Dochart, in one of which is a well-wooded island, where stands one of Rob Roy's strongholds, now a ruin. A mile further on we arrive at Crienlarich, where we are to take up our quarters. Having arrived at the inn, we found seated at one of the side tables a tall, thin gentleman, who, by his drawling remarks and off-hand manner, it could at once be perceived was a good sample of the bouncing Yankee. Fixing his keen, yellow eyes on me, he remarked—"Well, friend, I guess you have got a picture box with you. Going to photograph a bit, I see." "Yes," I said, "I want some studies of rocks, foregrounds, and, if possible, Highland cattle." "Ah," he said, "it is quite a picture." "What! the camera you mean?" "No! No!" he replied, "the country. You can see it all at once as a miniature. Guess, if I could get high enough, I could take a view of it all on one plate. Why, if you saw our hills, lakes, and falls, one of each would make all you have in this 'ere old country of yours. Why, our man are taller and our women fairer—" "And you talk much taller," I interposed. "Guess you'd like to see my box and tube—not the old thing you have here. I am rather scared to show it, as I wish to bargain the invention for a hundred dollars, I calculate, to pay my trip before recrossing the Atlantic."

And certainly it was not the "old thing," but a skeleton camera formed with some hinged pieces of wood for the bottom and front, and brass wires to fold for keeping a covering of india-rubber cloth up to form the square camera. In the sides of this cloth were sleeves for inserting the hands when changing the dry plates. On the top was a small red glass to see through, and also a red glass to put into his focussing frame. The pictures he showed me were very fine in detail, taken by the collodio-bromide process. "This is an improvement of my own," he said, "on Newton's process, and I guess I will be able to take all the colours with it slick off, and no more of you daubers and tarned painters!"

I tried hard to get this wonderful discovery from him, but all my efforts were useless. He got "scared" at me, and would say no more about it; but I have a strong opinion it was all a myth, as he appeared to be under the influence of our mountain dew. Meanwhile our party arranged to go to Loch Dochart, to fish for trout, till dinner time; and, getting out in two boats, we enjoyed ourselves, floating before the wind, and casting our flies in the water we hooked about two dozen fine trout. It is interesting to watch the flies skimming along the water, and the plunge of the fish at them; then you forget all else, and are at peace with all the world. Again, when pulling back to catch the wind you can watch the varying effects on the surrounding landscape.

I had brought my camera to take some views of the old castle, situated on an island in the loch, but I had been so absorbed in plying my rod, that I forgot all about it till one of the most striking effects I ever witnessed was brought before me. The crumbling walls of the old castle were in deep shadow, the light here and there tipping the prominent juttings, and glancing through the rich foliage of the variegated trees, which were reflected from the mirror-like surface of the lake. The adjoining hills were cast in misty haze, forming an indistinct background, and combining to produce a perfect ideal of a fairy scene of surpassing beauty. I called to my friends to pull for the shore that I might get a photograph of it, but they could not see it with my eyes, and would not be persuaded to leave off fishing, and when I got ashore the beauty was

gone. It had lost the sparkling light, and the once lovely scene was now a cold, grey, lifeless mass.

We resolved after dinner to go up the river—my friends to fish and assist me in photographing some Highland cattle. We at once made for the river side, where the cattle were feeding. Getting my camera placed in a corner of the field, my friends now commenced to collect the animals together and drive them towards the corner where the camera and I were placed. But no sooner were they placed in order than the undisciplined brutes would break their ranks, and rushing together make a furious stampede, as if bent on sweeping from the field with their long horns both myself and the camera. After several repetitions of this I managed at last to get one to stand quiet, and had it in the focus of my lens, but I was too near; it was too large for my plate. I took the camera and stand in my arms, my head still below the dark cloth, and, moving backwards, stumbled over a small bank, stand and camera going right over my head. On getting to my knees, I found that my friends and the cattle were all gone! In the distance, however, was seen approaching, with all his might, a Highland gillie surrounded by a number of collie dogs, and making straight for me with a determined grin—the collies yelping and showing their teeth, as if bent on using them on my poor carcase. The gillie roared out—“What the mischief you'll pe run the besties through the field for?” I explained in the mildest manner what I wanted; but he would not be reconciled till I brought out my flask, which is a balm for all the ills a Celt is troubled with. He then commenced to go in amongst the cattle, and it was astonishing to observe how obedient and soothed the animals seemed to become, as if they knew their protector. I got some very good pictures after a great deal of labour, but felt a little exhausted.

I threw myself down on a bank by the riverside, admiring the varying effects on the distant mountains. On looking up the murmuring river, the ripple dancing and reflecting back the golden rays of the declining sun, the rich peach-like bloom resting upon the mountains, and the bold, rocky foreground of the river, with the rich brown colour of the stunted oak, and deep dark green of the Scotch fir—and in musing reverie exclaimed—“Oh for a process by which these colours could be taken!” A voice near me said, “Come with me and I will show it you.” On looking up I could see my friend the Yankee bending over me. I rose and followed him to an old hut close by. We entered, he closed the door, and took off his long waterproof overcoat, and placed it against the chinks of the door to keep out the daylight. Taking a small dark lantern from his pocket, which threw a deep red, unnatural reflection on the old rafters, casting their shadows on the turf roof, he solemnly said, at the same time drawing himself up to his full length, and assuming a look of stern gravity—“You must swear not to divulge this secret to any living man.” He took a number of black boxes from his pockets, and also bottles, which I tried to get a smell of as he turned his back; but he was too sharp for me. He took one of the plates from a box, and I could perceive it was all of a glow with bright prismatic colours. He said, pouring on the plate a white liquid-like bromide emulsion—“The light will make the whites permanent in proportion to its intensity, and the colours on the plate will shine through and will produce a picture as bright as that outside, by the oxidation of the silver compound. The plate was exposed, and I stared in amazement as I saw the glowing colours of the original grow before my very eyes. I smell, taste, and feel for the causes, but none are apparent, except it be the fumes of alcohol, with a small trace of sulphur. I said—“It will not stand; it is the glow of this light that deceives the eye.” He said—“Take it to the door and judge for yourself.” I opened the door. O! magic! it is bright and glowing as the scene before me! I returned to the hut, and the Yankee appeared in my eyes much taller than before. “Are you satisfied now?” he asked; “I guess that

is tarned smart; and that, with my rapid dry plates, will be the process of the future. But that is not all. I have discovered a new reflector by which the rays are all concentrated on the sitter. I can take a picture by the ordinary gas in the darkest place with my gelatine plates.” Here he unfolded an old umbrella, the inside lined with silver foil; he threw it over his shoulder and turned out the red light. I could now see a blue haze gather round his head. It gradually got brighter until his eyes glared like two electric lights. The flame now poured out of his mouth and nostrils. It got more intense, and I could see his thin frame all ablaze. The light now became so bright and dazzling, and the heat so intense, that I put my hand over my eyes for protection, exclaiming—“It is not the Luxograph; it is spontaneous combustion!”

I awoke from my troubled dream, the sun shining right in my eyes, and as I struggled to realise my position again exclaimed—“I see it all now! He has been too often at the flask!” My ears were now filled with the loud laughter of my fishing friends all around, as one held the whiskey flask to my mouth, while another was putting a live trout down my back. They had hid all my apparatus. One had my plate-box in his hand with the lid open, and all my plates destroyed. Quite disappointed with this unlooked-for termination to my photographic tour, I immediately packed up my apparatus, inwardly resolving that if ever again I ventured on a similar “cruise” it should be with those able to appreciate the beautiful art.

While on this subject I may state that nearly all our great artists have been passionate anglers, and have drunk to the full the music of the murmuring ripple, or the wilder dashing of the breakers. And why is all this? Because in all these ever-varying aspects of the scene the artist has something to work upon—some new hint from the infinite phenomena of nature; and it is only as he is successful in transmitting these faithfully to his canvas that art becomes associated with the noblest aspirations of human genius. Robert Burns sums up the education of the poet in the following couplet, and the like may be said of the artist:—

“Gie me yae spark o' nature's fire—
That's a' the learning I desire!”

DAMAGING NEGATIVES.

A CASE of considerable interest to photographers occupied the attention of the learned judge of the Edmonton County Court for a considerable period on Friday and Saturday, November 7 and 8th. Mr. Chas. Tune (trading as Tune and Co.) a photographer, at the corner of White Hart Lane, Tottenham, sued Mr. Melhuish, photographer and secretary of the Photographic Association, of 12, York Place, Portman Square, to recover £7 10s. for printing photographs from negatives. Mr. Avery, solicitor, appeared for plaintiff, and Mr. Peckham, solicitor, for defendant. The latter admitted the debt, but set up a counter claim of £10 for damage done to certain negatives while they were in plaintiff's possession. The evidence in support of the counter claim was to the effect that when the negatives were sent to Mr. Tune in December 1878 they were in good condition, and that when they were fetched away on the 15th of October last, they were found to be useless through being injured (as was contended) by having been kept in a damp place while they were upon Mr. Tune's premises. The negatives were from three pictures by the old masters, and the prints were sold at eight shillings each without frames. The negatives, being valuable ones, had been kept in a separate room at the top of the house, and was a dry and otherwise suitable place for the purpose. In cross-examination Mr. Melhuish stated that the negatives were fourteen years old; that he did not see them packed before being taken to plaintiff, but knew that they were wrapped in paper; that it was absolutely impossible for any portion of the varnish to be rubbed off through the negatives being packed in paper; that they were not reticulated when they left his premises, and that it was possible to stop reticulation after it began, because it did not extend after the varnish became dry. In reply to the judge, Mr. Melhuish said the white spots on the prints from the negatives could be touched out, but that there was no means of removing the black spots, which had

been caused by the film coming off in consequence of the negatives having got wet after leaving his premises. The defence was that when the negatives were received by Mr. Tune, he found that reticulation had commenced; that certain repairs were done, and the printing executed; that the prints were sent home and paid for (the claim being for other printing done subsequently); that the negatives were then put in a room having a temperature of 110 degrees, where Mr. Tune kept his own negatives; that they had never been subjected to damp; that they had been left at the owner's own risk; and that the injury had been caused by the progress of reticulation, which, like mortification in the human body, could not be stopped after it had once set in, the original cause of reticulation being damp. The judge said the complaint of Mr. Melhuish was not that want of skill had been shown in printing, but that the injury to the negatives had been caused by the mode in which they had been kept after the copies were taken off. It was obvious, however, that they were in fair condition when the printing was done; the prints themselves proved that; but when they were returned three weeks ago they were in bad condition, therefore they must have become wrong in the interval. Mr. Tune, however, was not bound to keep them. They were sent to him for printing purposes only, and he kept them for the convenience of Mr. Melhuish and placed them where he stored his own, which was all that he could be expected to do. If there had been a continuous engagement to keep them the case would have been different; but Mr. Melhuish sent the negatives and agreed to fetch them away. Mr. Tune, therefore, was only an unpaid custodian, and had used all precaution to keep them in safety. Mr. Tune consequently was entitled to a verdict. Judgment was then given against the counter claim with all costs.

THE GELATINE PROCESS.

A CORRESPONDENT of the *English Mechanic* gives his experience in working the gelatine process. He says:—

Having worked at this process for four or five years, I give the following as the simplest and most convenient way of working which I have yet found:—For 3 ounces of emulsion take 20 grains of ammonium bromide, 8 grains of Nelson's fine-cut gelatine, or the No. 1 gelatine of the same maker. Place the ammonium bromide and the gelatine in an 8oz. or 10oz. hottle, and pour on 2 drachms of distilled water. In another ½oz. bottle place 30 grains of silver nitrate, and pour on 1½ drachm of distilled water; swirl it about until quite dissolved. Have a pot of boiling water holding about a quart. When the gelatine has soaked for ten or fifteen minutes, take the pot off the fire and let it cool down for five minutes or so; then introduce the hottle with the gelatine very gradually until you can let right down into the water without cracking.

When it has become thoroughly heated shake the bottle slightly, so as to mix the gelatine and water well together; then take all into the dark-room and drop a few drops of the silver solution into the bromised gelatine. Shake well. Then add a few more drops and shake again, and so on until all the silver is got into the gelatine; then wash out the silver hottle with ½ drachm of distilled water, and add it to the emulsion. Replace the bottle in the hot water, and cover it up with a cloth. Let it remain until the water is nearly cold, about two hours or more; then add 52 grains more gelatine. Turn the bottle about so as to well wet the fresh gelatine, and let it soak ten minutes, then dissolve in warm water. When the gelatine is all dissolved and thoroughly mixed with the emulsion, cork or stopper the hottle, and lay it, side down, in a pan or basin of cold water. Keep turning it round for a few minutes, when the emulsion, being very thick, will set in a film round the sides of the bottle. When quite set and firm, fill the hottle with cold water, and change three or four times during five or six hours, when the bottle may be turned upside down to drain for a few minutes; then add 1½ ounce of distilled water, dissolve by placing in warm water, filter into a four-ounce hottle marked at three ounces. A filter may be made by tying a piece of muslin over the neck of a bottle with the bottom cut off. Take a square piece of muslin, fold it in quarters, open it so that it forms a

conical bag; when filtering, let the point of the filter go just inside the neck of the hottle; add 3 drachms of mythylated spirit, and make up to the 3oz. mark with distilled water. Turn the bottle about until all the oily lines caused by the spirit are gone.

The emulsion is now ready for coating the plates. Pour a pool in the centre of the plate, incline the plate so that it flows all over (if any trouble is found the emulsion may be conducted over the plate with a strip of glass), return the excess to the hottle, letting the corner of plate touch the inside of the neck. Leave enough on the plate to form a pretty opaque film. Lay the plate down on a piece of plate-glass about two feet square, which has been levelled on three screws. Screwed into a block of wood and placed on a table, a board should be supported about an inch above the plate to catch falling dust. Four wood clamps at the corners of the plate will do, the back ones to have an upright piece, so that the board may be raised up like the back of a hook, as each plate is coated and laid down. During warm weather the coating must be done in a cool room, or there will be trouble in getting the plates to set. When set, place in a drying box, which should have draught of air conducted through it, or if the coating room can be kept dark they may be left on the glass plate or set up on end on shelves, when they will dry in ten or twelve hours.

These plates, in a good light, may be exposed about five seconds with a 9in. focus lens, ¼ in. stop or with a 4½ in. lens, ½ in. stop, as quickly as the cap can be taken off and replaced. They may be developed as follows:—To every drachm of a 2-grain to the ounce of pyrogallie acid solution add one drop of the following mixture: (1 drachm of water, 3 drachms of strong liquid ammonia, and 1 drachm of potassium bromide). If the plates have not been over-exposed this will develop them to printing density. Before development the plates should be soaked in cold water for a minute or two; when developed wash well and fix in saturated solution of hyposulphite of soda, again well washed, and left a quarter-of-an-hour, film downwards, in a basin of cold water; the corners of the plate coming against the round sides of the basin keep the plate near the top of the water, so as to allow the hypo. to soak out and fall to the bottom; they may then be set up on end to dry, *not* near a fire. I think the chrysoidine may be obtained at Judson's. What I use is dark red tissue paper, varnished with shellac varnish, as the front of a lantern which holds a small paraffine lamp.

"PHOTOGRAPHED LIKE THAT!"*

DOUBTLESS, many persons would be glad to bring the sun into the Libel Court. After an evening party, prolonged into the small hours of the morning, his Celestial Majesty (who, by the way, on this occasion is not to be confounded with the Emperor of China) frequently dispels the illusions conjured up by the most delicate *rouge* and the very finest *blanc de perle*. Yet, after all, the family brougham, or the less-aristocratic four-wheeler, afford ample and welcome shelter to those who desire to shield their charms from anything more searching than wax candle-light. But when the sun calls to his aid photography, the consequences are more serious, because longer enduring. The school-boy's earliest experience is the meaning of *littera scripta manet*, and the belle's last lesson, that it is a difficult matter to get rid of an unflattering negative. That this is certainly the case has been proved by the declaration on oath of the husband of one of the fairest of our beauties, that the threat of a solicitor (usually more efficacious than the aid of wild omnibus-horses) is powerless to prevent the appearance of popular cartes in fashionable shop-windows.

At such a time as this, when photography is claiming a large share of public attention, it will not be out of place to glance at some of the better-known sun-pictures, with a view to submitting them to a little amiable criticism. To deal harshly with an "arrangement" of forest trees, hatches

* *Life*.

unstarched shirts, and Mr. Gladstone, would be as cruel as, breaking a butterfly on the wheel, or writing something intentionally savage about the rather ludicrous demeanour of Sir Thomas Chambers in the lucrative character of Recorder of London. Again, actors and actresses should be free from hostile commentary when they appear on paste, instead of deal, boards. In an age of advertising, it is natural enough that eminent tragedians should desire to show their heads, and burlesque *artistes* their feet, to thousands of perambulating admirers. He who gazes upon talent in the shop in the morning, is frequently induced to stare at talent from the pit in the evening. The reigning goddesses of our *salons*, now that it is known that they are photographed against their will, should also be allowed to escape the reviewer's pen. Accidents will always happen, and it is a lady's misfortune, rather than her fault, if she be caught by an energetic operator in the midst of an artificial snowstorm, or in the act of trying on a "large and furry hat." But the matter is altogether different with public characters of the male sex. It would be absurd in the extreme to pretend, even for a moment, that statesmen, generals, and bishops, had been forced before a hostile camera. These individuals are free agents, and although the expression upon some of their faces certainly suggests the idea that a photographer is threatening them with a revolver, from behind a corner, while he offers them the choice of death or immobility, the chances are, that the scene of their martyrdom was, at any rate, disassociated with recollections of personal violence. Exception may be taken to this assertion on the ground that the *carte-de-visite* of the Premier was unquestionably executed "by Royal command." But then, it must be remembered, that when the Queen most graciously ordered Lord Beaconsfield "to be taken," Her Majesty, no doubt, left the details of the picture entirely in the hands of her distinguished subject. Lord Beaconsfield, and Lord Beaconsfield alone, is responsible for the strange wide-awake hat, the incongruous frock coat, and the duly obtrusive shirt collar. The expression of simulated interest in the advertisement sheet of the newspaper he is reading is also his lordship's own. The humour of the idea is quaint in the extreme, and serves as an excellent foil to the almost tragic poetry of the languid grasp in which the journal is wearily—oh, so wearily—held. But, taken altogether, the picture is disappointing. The levity of the shirt-collar is too marked, and the fun of the wide-awake hat too broad. Remembering the circumstances under which his portrait was being taken, Lord Beaconsfield evidently wished to perpetrate a harmless and dignified joke, calculated to raise a kindly patronising smile to royal lips. In this he must have failed, as his picture, to be frank, only proves him to be an author capable of sartorial buffoonery. Leaving the Premier, and turning to a photograph of the Leader of the Opposition in the House of Commons, a strange resemblance immediately appears. The expression of dignity is common to both. Lord Beaconsfield, however, is merely pretending, while Lord Hartington is severely in earnest. The heir of Devonshire glares indignantly, as if his pride had been trodden in the very dust by some one suggesting to him that he really ought to consent to appear as "the Third Officer," in the "Lady of Lyons," in some amateur theatricals. The angry fire in his left eye seems to say, "I will play Claude Melnotte, or—nothing!" A ferocious expression is also noticeable in the portrait of the Home Secretary, which is only half subdued by the prominent introduction of a pair of broad-rimmed spectacles. The Duke of Argyle appears with his head defiantly thrown back, with his hair flowing behind him. Lord Cranbrook adopts the same *pose*, but with considerably less capillary adornment than his noble model. The ample tresses and Byron-collar of Lord Salisbury, coupled with a certain sort of sweet melancholy in the gaze of the Foreign Secretary, foster the hope that some day his lordship may be inclined to publish a little hook of poems entitled, "Sighs from the Breast of a Stricken Gazelle." Mr. Smith, in one of his *cartes*, appears with his hands thrust in his trouser pockets, nourishing

the impression that he is, several inches of him, a sailor. It will be evident at once that it is most desirable that a First Lord of the Admiralty should leave this nautical idea firmly planted in the public mind. Turning from the State to the Church, several *cartes* appear under the heading of "The New Cardinal." A glance discovers that it is John Henry Newman, wearing the same costume as His Eminence of Westminster, Dr. Manning. Some time ago, a photograph was published of the Head of the Birmingham Oratory, in which the Professor was depicted with an expectant smile upon his lips, as if he were waiting to hear a joke or a good story. The present portrait appears to be a sequel of the former one. His Eminence has heard the anecdote in this picture, and seems to be observing with gentle melancholy, "Come, come, it won't do. Your narrative is as old as the hills. I heard it years before I went to Oxford. Now, don't speak—I know what you are going to say. You are about to ask me when a door is not a door? Take my word for it, my good young man, I really know the answer." Close to the latest made English Cardinal is usually found the Bishop of Rochester, who seems to be divided between surprise at finding himself photographed, and determination in maintaining his dignity under the exceptionally trying circumstances of the case. Dr. Parker, of the City Temple, appears in long flowing locks, contrasting forcibly with the neatly arranged "head of hair" of the Reverend Newman Hall. The latter Reverend gentleman assumes an attitude evidently roughly copied from the pose of a bishop of the fourteenth century blessing his flock. After gazing upon this rather cramped position, it is quite a relief to turn to Mr. Spurgeon, comfortably seated upon a very easy chair. Turning from the Church to the Army, the most remarkable portrait reveals itself in the likeness of Lord Chelmsford. This well-known warrior is found in an admirably cut suit of mufti and an anti-regulation beard. The right hand of his lordship rests upon a gigantic book (apparently, a pantomimic edition of the *Field Exercises*), and with his left—doubtless in the absence of a Field Marshal's baton—he clutches at a packet of long-shaped envelopes. It is almost startling to find a tactician of such world-renowned eminence so gentle in appearance, and seemingly so simple, as, certainly, not one man in a thousand would guess that Lord Chelmsford had proved himself a second Wellington. Sir Garnet Wolseley "tones down" a very evident shooting coat, with a dozen and a half of the best and most honourable of Orders. But the hero of the hour among the warriors is, without question, Captain Carey. This gallant officer also (strange to say) assumes mufti, and relinquishes the well-used sword for a walking stick. The ex-King of the Zulus is occasionally seen, or rather his head, as Cetewayo's photographs, in European costume, have not yet reached this country, and, for the moment, the full dress of His Majesty is most likely unconventionally scanty. The portrait of Mr. Ruskin, to turn to Art, is remarkable for a curiously-constructed waistcoat, which the author of the "Stones of Venice" apparently is anxious to force upon the attention of the public. Poetry is represented by Mr. Alfred Tennyson in an old Inverness cape of quaint design, but not very imposing appearance. But, perhaps, the most interesting portrait in the collection is the likeness of Lord Lorne, for it fully accounts for the sudden departure of the Marquis to Canada. After gazing upon the wonderfully-trimmed overcoat assumed by his Lordship, with its eccentric sleeves, huge collar, and gigantic buttons, it becomes plain, to the meanest apprehension, that such a garment could not possibly have been worn in England.

Columbus might be filled with further remarks upon the photographs in the shop-windows, but, from a few, learn the rest. However, it is satisfactory to note that, until the secret of taking portraits with the aid of the sun is lost, there will be plenty of subjects for creating laughter. So long as popular men patronise photography, there will be no lack of suggestions which may be turned to good account on the 5th November.

PHOSPHORESCENT PHOTOGRAPHS.

SOME months ago, we gave in these pages details of the method which Mr. Woodbury had devised of producing phosphorescent photographs—pictures which were self-luminous in the dark. The method Mr. Woodbury found successful consisted in using the powder process, sometimes described as the "dusting-on" process, using a phosphorescent powder to adhere to the tacky image formed by exposing a bichromated syrup under a cliché. Herr Warnerke has not been successful with that method, but he has employed a still more simple plan of securing his luminous picture. He simply takes an ordinary transparency and backs it with a plate coated with the phosphorescent substance, which, showing through the lights or transparent parts of the photograph, at once gives a luminous image in the dark.

The substance used by Mr. Warnerke was sulphide of calcium. It should be borne in mind that these substances are not self-luminous, but have the power of absorbing and storing up light which has shone upon them. A plate coated with such a substance exposed to sunlight will, if placed in contact with a negative and a sensitive plate, be found to have actually stored sufficient light to print an image of the negative on the sensitive plate. An American contemporary, referring to the matter, says:—

"Two patents have been recently taken out in England for phosphorescent powders. One of the patentees states, in his specification, that his object is to obtain and utilize at nighttime the light absorbed during daytime from sunlight or an artificial light, either by employing the powders after exposure, or by augmenting their brilliancy by means of electricity. The powders are made by taking 100 parts by weight of carbonate of lime, and phosphate of lime produced by the calcination of sea shells; secondly, 100 parts of lime rendered chemically pure by calcination, and after the above are mixed, 25 parts of calcined sea salt are added, then 25 to 50 per cent. of the whole mass of sulphur incorporated therewith by sublimation, 3 to 7 per cent. of colouring matter in a powdered form composed of mono-sulphuret of calcium, barium, strontium, uranium, magnesium, aluminium, or other minerals or substances, producing the same appearances, *i.e.*, which become luminous in the dark. The other patentee says of his phosphorescent substance, that he prefers calcined oyster shells combined with sulphur by exposure to sufficient heat, or a paste formed of neutral arseniate of baryta and gum tragacanth or sulphide of strontia, or sulphide of barium in combination with a small percentage of magnesia. For rendering walls or surfaces for advertising or other purposes luminous in the dark, they are coated with an adhesive substance. The phosphorescent substance is then spread over the surface, and then coated with transparent varnish or other transparent substance."

PHOTOGRAPHIC VISITING CARDS.

WHEN the carte-de-visite portrait was first introduced to the public, the intention was that it should be actually used as a visiting card. Whether it was ever practically employed for such a purpose to any appreciable extent we cannot say; but if it were, the practice never obtained generally. The pretty little portraits were treasured and preserved, and at one time acquired temporarily a new name, being preserved in albums, and called album portraits. The name carte portrait was, however, generally retained, although the idea of using them as real visiting cards had passed away.

It appears there is some probability of the idea being revived. A correspondent of the *Queen*, in a column devoted to "Etiquette," says:—"Send your visiting card by post in the shape of a photograph—a true carte-de-visite—which would be not only a reminder, but an interesting one, and which would give rise to conversation and criticism such as now follows a personal visit, but sooner over. Let the costume of the portrait define the nature of the 'call'; if very distant, send a card in evening or court dress; if more friendly, send one in visiting or walking dress. It might be *de rigueur* never to send the same impression, and thus the expense involved would be as flattering as the hire of a brougham or the waste of half a day. No bad notion this, and one which might lead to a painless reform."

If such a plan become the fashion, it will inevitably give increasing occupation to the portraitist, especially if, as suggested, it be made *de rigueur* never to leave a second impression from the same negative. The idea is a good one, and photographers of taste may facilitate its adoption by devising a neat effective style for the portrait and card, for a special style will be necessary. The ordinary card portrait mounted on a coloured enamel card, and covered at the back with the advertisement of the portraitist, would never be adopted. A neat white—or, it may be, cream-coloured—card with space for the written or engraved name, and a small but pleasing style of portrait, is what is required. Above all, the thing must not be loud or vulgar. Something neat and unobtrusive is desirable. Here is opportunity for the photographer with taste to exercise his invention. If such a fashion were once generally adopted in society, a steady and permanent addition to the occupation and income of many photographic portraitists will be secured—a point certainly worthy of consideration.

THE PHOTOGRAPHIC EXHIBITION.

WE have before remarked that portraiture did not constitute so prominent a feature of the present Exhibition as of many preceding ones; but there is, nevertheless, much good work in this important line. America sends us some of the best. The time was when we looked to America for special excellence in technical effects: brilliant, clean, sharp photography was frequently produced in America, but few persons thought of looking for the highest examples of art photography beyond the Atlantic. This has of late years been considerably changed, and in portraiture, at least, we find especial art qualities present in the examples of American work which come under our notice. On the tables, unframed, will be found a fine collection of the portrait studies of Mr. Napoleon Sarony, an English photographer in so far as he commenced his photographic career in this country, but resident in New York, and as a photographic portraitist, probably not surpassed in any country. Freshness and originality of pose, grace of outline, and richness of light and shade, characterize his work, and, so far as we can judge, faithfulness of likeness is not sacrificed to the more showy characteristics. Of the portraits shown is one of a charming English actress—Miss Ada Cavendish—which is admirable as a likeness. Mr. Sarony's portraits are mounted in a style which is well worth attention, but which has not hitherto been received with much favour amongst English photographers. The print is

mounted very nearly close up to the edge of a stout piece of cardboard, about one-eighth of an inch thick, the edge of which is bevelled towards the front, and gilt. Large prints, whole-plate, and of a size much longer, are so mounted, and are very effective.

Even the West of America has become a pioneer of art progress. Mr. Roher, of Chicago, has sent a fine display of portraiture of all sizes, from cabinets upwards, and all exceedingly good; perfect technical photography is present in every frame, and very high art qualities in many. Like the works of Sarony, these are distinguished by freshness and originality of pose. If we were disposed to find fault, we might say that at times there is a little too much straining after action, many of the full-length figures being engaged in doing something in which the action is apparent; and suspended action in a picture is apt to become irritating. The large pictures—sixteen by twelve and upwards—are chiefly of full-length figures of ladies; and the grace, beauty, and elegant dress of American ladies lend themselves materially to artistic effect in the pictures. The interiors—which, for the most part, form the backgrounds of the portraits—are well managed and well subordinated, all aiding the primary aim and motive of the picture—the portrait. In some of these pictures there is a slight tendency to blackness, from deep printing, we think. Two we have especially marked as free from this, and having a fine sense of space in the room interior in which the figure stands; these are a portrait of Miss Emma Thursby (285), and one entitled "Departing" (313). The work is so good throughout, that we are glad to congratulate Mr. Roher on his well-earned medal.

Baby portraiture is a prominent feature in the present Exhibition. Mr. Faulkner, the prince of baby-portraitists, has not given us one of his usual large frames full of infantile charms; but he has sent a few studies of rare beauty, alike as photography, art, and childhood. His series of portraits of royal children, printed in red, after the fashion of Bartolozzi's well-known engravings, are very beautiful. The children, in spite of their royal birth, are really very pretty—some of them exceedingly charming—and the portraiture is in Mr. Faulkner's best style, whilst the exquisitely luminous quality of the red pigment prints is singularly satisfactory. The studies of expression in similar style are equally fine. Mr. H. J. Byrne's frames of child portraiture, produced by the aid of gelatine plates, are very excellent indeed, displaying fine photography, and admirable management of children. Mr. W. E. Debenham also has very good examples of children's portraiture produced by the aid of gelatine plates. The various examples of portraiture on gelatine plates are in no wise inferior to those on wet collodion. A frame of cabinet and carte portraits (89), the negatives having been taken on these plates by Arthur King, are excellent. Two frames of similar portraits from gelatine negatives by E. Gregson and Sons are also very excellent. The portraits from gelatine negatives exhibited by Mr. Cowan—or, to speak by the card, by Messrs. Hill and Saunders, of Porchester Terrace—are more than excellent. The pair of upright pictures (106 and 128) are singularly fine. They are printed on opal glass in carbon, and the first named is interesting to photographers for an element of effect worthy of note. A delicate tint surrounds the image, very similar to an india tint. This tint is obtained simply by the aid of the "safe edge" of the carbon tissue, which is transferred to the opal, leaving a margin of clean opal beyond. The boy's portrait (128) is unsurpassed by anything in the Exhibition by the grace and ease of the pose. It is well worthy of examination for the mode in which the painted floral effects on the background screen are combined and supplemented in the most natural manner by the real accessories placed beside them. The picture is a gem in every respect, and most worthily wins its medal. Some other carbon prints from gelatine negatives (288) by the same firm are also exceedingly fine. The portraits by the powder process (238 and 275) by the same firm are very

charming. Portraits from gelatine negatives, taken in an ordinary sitting room, by W. Cobb and Son, are very good for the conditions; but the effect of the lighting is somewhat heavy. A frame of large portraits (137), by M. Boucher, of Brighton, is very noticeable for the general richness of light and shade, and for the excellence of each portrait when examined in detail. The frame consists of half-a-dozen portraits, all very fine. No. 1, "The Aga's Favourite," is also our favourite. No. 2, "From Erin's Green Isle," is also exceedingly charming. The portraits are in what has come to be known amongst photographers as the Salomonesque style, which is distinguished by largeness and massiveness of manner. These, for highly-finished portraits, are singularly free from retouching. There are several examples of portraiture by the aid of artificial light. Of these some very excellent specimens are exhibited by the Luxograph Company, and several others by the same light are contributed by Mr. G. E. Alder, which are very excellent indeed, and apparently in no way distinguishable from portraits by ordinary daylight. Various examples of the work of the electric light are sent by Mr. Vander Weyde. The skill of an artist of considerable taste is manifest in these, and the lighting, although a little peculiar in some, is very effective. Mr. Hazard's frame of portraits in fancy dresses by artificial light contains some excellent photographs. It is a pity the effect of the frame is marred by the bizarre arrangement of the pictures. The same is true of a frame of good portraits by Mr. J. S. Catford. Several very fine examples of large portraiture sent by Messrs. Thomas and Robert Anon, Professor Rainy, M.D., Lawrence Hill, Professor Lister, and Dr. Dixon, are all noble examples of portraiture, in a style worthy of the distinguished men portrayed. James Russell and Sons send some very fine examples of portraiture, one of which, a group of three ladies (229), has been distinguished by a medal. A frame of cabinet portraits by Lombardi is very good, and a similar adjoining frame, by Barry and Co., is very excellent. A series of four frames, entitled "Little People and their Pets" (268 to 271), by G. Watmough Webster, consisting of portraits of children and their dolls or other toys, is worthy of very high praise for their rare excellency. The number of portraits is very large, and the variety of effect, and good effect, is amazing. The portraits are full of action and expression, and display much tact and skill, as well as artistic feeling and mastery of photography. Lombardi has some very fine large portraits, 277 to 279 being excellent examples. H. S. Mendelsohn has a fine frame of studies taken on dry plates, containing some excellent work. Mr. Hubbard has a fine portrait of a lady (294), unfortunately skyed beyond examination. Mr. P. M. Laws sends some good examples of gaslight portraiture, which will be examined with interest. We think, however, that he has not sent his best examples. Mr. Baker sends children taken on gelatine plates, which are very good. Mr. Fry has a frame of good portraiture on gelatine plates. In some cases, portraits and *genre* studies run so much in the same groove that we have probably left some portraits to be noticed as subject pictures. These will duly come in a future issue.

FRENCH CORRESPONDENCE.

THE IRON AGE OF PHOTOGRAPHY—PROGRESS OF PHOTO-TYPY—UNION FOR THE PROMOTION OF THE TRADE INTERESTS OF PHOTOGRAPHERS—NEW WORK ON PHOTOGRAPHY WITH GELATINE.

The Iron Age of Photography.—At the last meeting of the Photographic Society of France there were read two highly interesting papers, the one by M. Poitevin, the other by M. Henri Pellet. In both of these papers processes were described for taking positive photographs depending on the application of a salt of iron. Oxalate of iron is used as a developer in the new gelatino-bromide

processes, just as the sulphate is used for the same purpose in those depending on wet collodion. Recently I called the attention of my esteemed readers to a process for taking Woodburytypes, in which is used gelatine rendered insoluble by the application of iron perchloride mixed with a little tartaric acid. The gelatine thus made insoluble is again rendered soluble by the action of the luminous rays. From these few instances which I am able to adduce, and which I could easily make more numerous, may we not conclude that we have at length arrived at a time—or, rather, we have reached a stage—in the life of the photographic art, which will one day, perhaps, receive the name of the iron age? Not that the age of silver is past; on the contrary, it still exists, and in an improved condition, by the employment of gold and of platinum; but, at any rate, we are approaching a period when iron would seem to be about to occupy a more important position in photography—a position where it will reign supreme by the side of and jointly with two other bodies: one carbon, partly belonging to the mineral, partly to the organic kingdom; the other, gelatine, belonging to the organic kingdom alone. The process for taking positive prints described by M. Poitevin endeavours to realise a more economical method of obtaining the pictures by utilizing the reducing action of a proto-salt of iron on some easily reducible substance like silver chloride. In effect, however, this method is new neither in theory nor in practice; iron sulphate has a powerful reducing action, of which advantage is taken to make visible the latent image impressed on silver iodide. So also iron oxalate is used for reducing in Willis's platinum process; and the same organic salt is made to play a similar part in developing a negative on gelatino-bromide; all of which brings us back to the point from which we started: the employment of the reducing action of the salts of iron for obtaining prints, either in Prussian blue, as in the *cyanofer* process of M. Pellet; or in black, as in the ordinary negatives by the ferrocyanide method; or as in the present plan proposed by M. Poitevin. Of all these reactions of iron, the most interesting will, no doubt, be that which will make possible a new *inverse* process of phototypy or carbon printing. I say *inverse*, because, by such a process, we should take a positive image from a positive, while in the ordinary processes a negative is required, in order to obtain a positive. Unfortunately, when the gelatine films have been rendered insoluble by immersing them in a bath of iron perchloride and tartaric or citric acid, their sensitiveness is very considerably reduced; such a film of gelatine, even when very thin and slightly coloured, requires an exposure of a quarter of an hour to direct sunlight in order to acquire complete solubility. In the first place, therefore, we must try to increase the sensitiveness of these films. There is no doubt that this object will be attained, and we shall then possess a very effective photographic process, founded on the principles established by M. Poitevin, enabling us to work with sensitized papers, which, as the gelatine is first made insoluble, will have the advantage of being capable of keeping for an indefinite period of time. One of the most important questions, therefore, which present themselves to our scientific photographers is the discovery of a substance which can confer greater sensitiveness on the gelatine film, that has been rendered completely insoluble by a salt of iron, when exposed to the action of the luminous rays. The principle laid down by Poitevin is a true one; of that there can be no doubt, for it is capable of proof. But there still remains something to be done in order that it may produce practical results, and that something is to render more sensitive the films of gelatine that have been previously made insoluble. I think we may consider it certain that this object will ultimately be attained, and we shall then have made another step in advance, and shall have given our modern stage of photography a further right to the title of the iron age.

Progress of Phototypy.—Some specimens of artotype, the name by which the process of phototypy is known in

the United States of America, have been sent to me by Mr. Wilson, the able and intelligent editor of the *Philadelphia Photographer*. A careful examination of these photographs, which were produced in the studio of Messrs. Harroun and Bierstadt, show that phototypy is practised with very considerable success in the new world. Prints of the same kind are also produced in Germany, especially at Munich, by Herr Obernetter, and the American samples which I have in my possession seem to be quite of equal excellence with those that came to us from Munich. They have quite the same appearance, so that I am induced to believe that the process by which they have been taken is no other than that of Herr Obernetter himself. In England, where this special branch of our art is far from having attained that stage of development which it merits, there are also excellent results, which challenge universal admiration, produced by this method under the auspices of the Autotype Company. The more I examine these beautiful results the more decided is my conviction that this process stands first in point of usefulness and general adaptability; all the other processes are but auxiliary methods serviceable under certain circumstances; but for obtaining a number of prints on a really commercial scale there is no other photographic process to which we can have recourse except that of phototypy, under whatever name it may be worked.

Trades Union for the Photographic Industry in France.—My esteemed friend M. Stebbing, in a letter which he has written to the *Moniteur de la Photographie*, praises the *esprit de corps* which animates the whole body of photographers in England, as illustrated by the handsome subscriptions, by Mr. Henderson and others, in aid of the establishment of a photographic club. In France the same spirit no doubt exists, but the manifestations of it are far from being so spontaneous as they are with you. I am in hopes, however, that some steps will soon be taken to arouse this spirit, and the formation of a union, embracing all the photographers of France and her colonies, which the *Chambre Syndicale de la Photographie* is now actively engaged in promoting, will afford a good proof of its existence. My own idea is, that a representative body should be established at Paris, a body which would have an influence in proportion to the number of members who belonged to it. Such a union is a matter of necessity for an industry which is still too young to have traditions to look back to, so that no organization exists, either legal or administrative, corresponding to the wants of the profession. A special organ in the press, devoted exclusively to the commercial and industrial interests, will serve as a bond of union between all the members of this general guild, and thus a void would be filled, and the wishes would be met of an important profession which already numbers more than 5,000 members, and which does business annually, on an average, amounting to between twenty and thirty millions of francs. This proposal, which I brought forward at the last meeting of the *Chambre Syndicale*, was unanimously approved by all the members present, and all that now remains to be done is to put it into practice. A committee will be nominated for this purpose, and soon we may hope to see a photographic union in active working order, always ready to help and promote all efforts in furtherance of the study of our art, and to defend the interests on which rest the prosperity of our profession; always anxious to stimulate the industrial, and, consequently, technical progress of photographic science. Though we cannot reckon on so large a material assistance as that mentioned by M. Stebbing in his account of the establishment of the English club, we may at any rate rely on a considerable contribution of good wishes, and that will be sufficient, for the present at all events, to attain the object in view.

New Work by M. Chardon.—Yet another book on photography has been published by M. Gauthier-Villars; this time it is a description of the gelatino-bromide of silver process as worked by M. A. Chardon. It would be superfluous to repeat here how conscientious this author is in all

the work that he undertakes, and how all that he says is always worthy of our best attention. In the instance before us it is easily seen that the abandonment of collodion-bromide of silver, notwithstanding its comparative slowness, falls heavy on M. Chardon's heart; he does not wish to give it up altogether, but he feels that though the collodion process has, and always will have, some good in it, gelatine emulsions cannot possibly be ignored, so he does his best to study the latter exhaustively. There is, perhaps, nothing absolutely new in this little tract, but it contains a correct and clear general account of the process, which can only be read with profit. In time we shall no doubt realize the improvements which this beautiful process still lacks, and then the last doubts of our learned colleague will be removed.

LEON VIDAL.

SACCHARO-SULPHATE DEVELOPER.

THE saccharo-sulphate developer, first recommended in the NEWS finds favour in France. *The Moniteur* says:—"Mr. Darricau of Marseilles sends us the formula of a developing solution through which, he says, a wonderful rapidity is obtained. Here it is:

Distilled water	100 c. c.
Saccharo-sulphate of iron	12½ grains
Acetic acid, crystallizable	50 drops

"This developer imparts to clichés a very rich tone, similar to that obtained from pyrogallic acid with a light equal to that required for such processes as that of Boissonnas and others. To open and close is sufficient to obtain a cliché which needs no intensifying.

"Mr. Darricau tells us next, how to produce this organico-metallic substance which dealers in photographic materials have not on hand. Take—

Proto-sulphate of iron	200 grams
Distilled water, boiling	100 "

Dissolve. Then take—

Rock candy	50 grams
Distilled water	30 "

Dissolve.

"Next, mix those two solutions, and the bluish light-green crystals are precipitated. These are gathered and set to dry between the folds of several sheets of white blotting paper, taking care not to use rose or buff-coloured blotting paper. (This is an essential condition).

"The addition of a small quantity of formic acid to this developer would, we think, intensify its action."

HOW TO AVOID SILVER STAINS.

BY J. E. BEEBE.*

PROBABLY the most unpleasant feature connected with photographic chemistry is the unavoidable staining of silver. Most unpleasant it is, both to operator and sitter; and having been able, by a simple expedient, to avoid this annoyance almost entirely, I take this opportunity of bringing it to the more extended notice of the profession.

Near the sink where the negatives are made, I have standing an ounce vial of ordinary tincture of iodine (the vial has, of course, a ground-glass stopper), and while my hands are still wet from the washing of the negative, I shake the bottle, and, with the stopper, stear all stains on my hands with the iodine. Now as to the result.

If my negative has been washing under the tap during the moment I am putting on the tincture, and I proceed to cut it with cyanide, of course by allowing the cleaning solution to run over my finger ends, they are at once freed from all stains. But I find that by using the iodine after each negative is made, and at once, before the silver has time to penetrate very far into the skin, and by a frequent use of good

* Philadelphia Photographer.

soap and water, the silver and iodine stains disappear without the use of any cyanide at all.

It takes longer to describe this simple operation than is consumed in doing it, and by a most ordinary economy of time the busiest operator need not lose a moment.

This is a small matter I know, but it may be of use to some photographer who appreciates how much disgust the usual soiled hands inspire, for very many people believe the black colour bomes off on their faces or dress, and will aid him in the neatness so essential to success.

A little more neatness as regards spotted clothes and linen would not be amiss, and then the usual trade-marks would be relegated to the resting-place of long hair and mighty hats, and it would be impossible to distinguish a photographer from any other gentleman.

Correspondence.

PHOTOGRAPHIC EXHIBITION.

SIR,—The writer of "In and Out of the Studio," although not mentioning my name, evidently hurls his shaft at me. If one did not grumble, abuses would never be rectified; but his argument is *nihil ad rem*. What I complain of is, not that the Council of the Photographic Society frame rules of which I do not approve, but that, having made certain rules, they do not abide by them, or give timely notice of their inability to do so, and not deceive intending exhibitors, as in this instance, or take advantage of their credulity, as would have been my case had I been simple enough to send my sovereign for so much wall-space, while the more 'cute fellow sends his pictures, and leaves the Society to apply for their charge, knowing that they will not do so, as they cannot afford risking his withdrawing his exhibits. Better not make any rules whatever than pose in this undignified position.

The writer goes on to state that one of the advantages common to both amateurs and professionals is in the fact of their having their work placed side by side with that of the best workers, and in the notice taken of it by the Press.

The first argument would be of some weight if the best men exhibited, which, as a rule, they don't; the second is of doubtful value, seeing the abysmal ignorance displayed by the London Press on all matters photographic; and, further, unless you happen to be in the "set," you have not the slightest chance, no matter how good your work may be, of getting it noticed. As an illustration, I may mention the regularity with which a certain gentleman's productions are commented upon in all the daily and weekly London Press being quite something phenomenal.—I am, sir, yours obediently,

JOHN VAUGHAN.

1, Cheshunt Terrace, Iffley Road, Oxford.

PHOTOGRAPHIC MEETING.

DEAR SIR,—In the last issue of your valuable paper an error happened in the report of the proceedings of the Photographic Society of Great Britain. The facts reported are not only incorrect, but they at the same time permit of a conclusion the very reverse of flattering to me personally. I permit myself to state the correct version of the incident. In consequence of the personal application of the Assistant Secretary to read a paper at the November meeting, I wrote a rather elaborate article on Actinometers, and not only I have been perfectly prepared to read it, but I wished to go as far as possible with reading, knowing that, the paper being extensive, I should require fully two evenings to read it. Our President, wishing to close the technical part of the meeting, in order to give more time to the informal conversazione, asked me to interrupt my paper, and postpone the completion of it till December. Conforming myself with that desire of the President, I asked to do so at a more convenient point, and after I completed the description of the electro-actinometer I stopped.

There is also another error, in the diagrams illustrating my paper read at the South London meeting. The parts forming the camera stand, instead of being drawn in their respective positions, are scattered about, some represented as upside down, which cannot fail to produce perfect confusion.—I remain, dear sir, yours faithfully,

10, Linden Grove, Peckham Rye, Nov. 16. L. WARNERKE.

[In the brief report of the meeting which our space and the limited time permit, we simply record the fact that only a portion of the paper was read; we have not space or time for unimportant details. We cannot agree with our correspondent that the record appears the reverse of flattering to himself. Surely it is less flattering, if that element can at all enter into the case, that he should be requested to leave off by the President, than that he should do so of his own intention. The placing of the diagrams in the South London report is also explained by the necessary economy of space, which has induced our draughtsman to pack them so as to occupy as little space as possible. We do not think any confusion can arise to those interested in studying the arrangement.—ED.]

COPYRIGHT.

DEAR SIR,—There is much difference between the meaning of the word "right," and "copyright." Copyright is defined in Worcester's dictionary in about a dozen lines, while the word "right" occupies about two columns. As this is a matter of some importance, it would be instructive if you would kindly explain why a photographer may not have the right to print from his own negatives, while the other has the copyright in the prints. In Mr. Bassano's letter the last five lines express the same idea as I wished the last five lines in my letter to convey.—Yours truly, A. BROTHERS.

[Copyright exists in the design of the picture, and cannot exist in the print apart from the negative, nor in the negative apart from the print. There are no rights in the case, except such as are created by statute. Hence discussion of abstract right amounts to nothing.—ED.]

Proceedings of Societies.

PHOTOGRAPHIC CLUB.

At a meeting of photographers held at the Freemason's Tavern on Friday, the 7th November, 1879, Mr. JABEZ HUGHES in the chair,

The CHAIRMAN stated the reason of calling this meeting, and the aim and object of the proposed club, and called upon Mr. Cutchey to read the report of the preliminary committee appointed at the meeting held at Mr. Brittlebank's on the 1st October.

Mr. CUTCHEY then read the following report:—

"Report of the Preliminary Committee of the Photographic Club, read at the meeting held at Freemason's Tavern, November 7th, 1879.

"As an outcome of the meetings held during the summer months at Mr. Brittlebank's, the want of a society that should combine the social with the strictly business element was greatly felt, and the subject, once mooted, was rather warmly taken up, and the idea of forming a Photographic Club was at once started, and several gentlemen promised subscriptions in furtherance of this scheme, one gentleman in particular offering one hundred guineas as an earnest of his views; and accordingly, at a meeting of photographers held at Mr. Brittlebank's, Tottenham Court Road, on the 1st of October, Mr. A. L. HENDERSON in the chair, the following resolutions were passed. It was proposed by Mr. C. G. Cutchey, and seconded by Mr. P. Mawdsley: 'That in the opinion of this meeting it is desirable that a Photographic Club be formed.' This was carried unanimously. Proposed by Mr. E. W. Foxlee, and seconded by Mr. Cowan: 'That no one be eligible for membership unless he be a member of a photographic society.' An amendment was proposed by Mr. Payne Jennings, and seconded by Mr. Lowrie: 'That though it would be advisable that the members of the club should be also members of some photographic society, this

should not be imperative.' A further amendment was proposed by Mr. W. B. Bolton, and seconded by Mr. T. J. Pearsall: 'That the membership be open to all.' Upon a show of hands the original motion was carried. It was proposed by Mr. Foxlee, and seconded by Mr. Mawdsley: 'That a committee be formed consisting of nine members, five to form a quorum, to carry out the preliminary arrangements.' The following gentlemen were elected to form a committee:—Messrs. A. L. Henderson, W. B. Bolton, A. Cowan, Payne Jennings, A. Brittlebank, E. W. Foxlee, E. Dunmore, P. Mawdsley, and C. G. Cutchey. It was proposed by Mr. Bolton, and seconded by Mr. Cowan: 'That the resolutions passed at this meeting be subject to such modification as the committee may deem desirable, such modification to be submitted to a general meeting.

"The Committee thus formed have met every week since; the first meeting having been on the 9th of October, when Mr. Cutchey was asked to act as secretary *pro tem.*, and numerous letters have been written to photographers and others.

"The original idea was to take a suite of rooms and establish a club, to be open at all times to its members. This idea, however, at present, your committee feels to be impracticable; but doubts not that in time this Club (if established) will be able to do so; but at present it must be content with a room for the purpose of meeting once a week, say on Wednesday evening at 7 o'clock, one hour to be devoted to formal business, and the remainder of the evening to social intercourse, the chairman to be changed each evening, and then only to take the chair for the time of the formal discussion. It is also hoped that a library may be formed for the use of the members, and that any novelty in connection with photography will find a place in what may be termed a museum; in short, that the Club may be, so to speak, a home for photographers. These ideas may seem Utopian, and in the far distance, yet without some such beginning as it is to be hoped will be made tonight would still be in the womb of time.

"The committee now place before you the following suggestions.

"That a club be formed to be called the 'Photographic Club.'

"That the subscription be one guinea per annum, and an entrance fee of one guinea in addition; this fee, however, not to be paid by the first one hundred joining.

"That all residing and carrying on business at a distance of fifty miles from London be considered as country members, and pay a subscription of half-a-guinea only in addition to the entrance fee.

"In order to test the feeling of photographers generally, an informal meeting was held on the 15th of October, when the resolution as to members being of necessity members of a photographic society was fully considered and discussed, and the feeling of the meeting was strongly in favour of the withdrawal of this restriction, and the Club being thrown open to all interested in photography, whether professional, amateur, or manufacturer; and your committee therefore calls your special attention to this resolution, and asks your instructions thereon.

"The committee felt that a very strong interest in the movement was taken by Messrs. Cobb, Warnerke, and York, and they therefore, in the exercise of the usual powers claimed by all preliminary committees, asked those gentlemen to join them in their labours.

"The committee have also drafted a code of rules for the guidance of the proposed club, and which rules they now submit to you, either for your consideration and discussion, or for the consideration of the committee you may to-night appoint."

It was then proposed by Mr. Payne Jennings, and seconded by Mr. A. L. Henderson, that a Club be formed, to be called "The Photographic Club."

The meeting then discussed and adopted the following proposed rules submitted by the preliminary committee, after which the following gentlemen were elected as officers for the ensuing year:—

Trustees—Mr. A. L. Henderson and Mr. Frederick York.

Treasurer—Mr. E. Dunmore.

Committee—Messrs. W. Bedford, Payne Jennings, A. Cowan, L. Warnerke, and P. Mawdsley.

Hon. Sec.—C. G. Cutchey.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held in the Religious Institution Rooms, Buchanan Street, on Thursday evening, the 6th inst., Mr. A. ROBERTSON in the chair. The minutes of the previous meeting having been read and approved of,

It was moved by Mr. T. GILFILLAN, and seconded by Mr. URIE, that the meetings be held fortnightly instead of monthly—Thursday being agreed upon as the most suitable evening.

Mr. GILFILLAN asked what had been done by the committee appointed to look out for a presentation picture, and as nothing had been done a new committee was appointed, viz.:—Messrs. J. J. Long, J. Urie, A. Robertson, and T. Gilfillan, to bring up a report at next meeting.

The following gentlemen were duly elected members:—Messrs. W. C. Hume, W. Preston, J. R. Glenzie, W. McGhie, J. Bourke, R. McColl, and Dr. Bell.

Mr. JOHN URIE, Sen., then read a paper entitled "The Mishaps of a Photographic Tour" (see page 554).

Messrs. BELL, McLELLAN, and GILFILLAN expressed their thanks to Mr. Urie for his amusing paper.

Mr. JAMES MCGHIE (Secretary) said that it was with feelings of pleasure he rose, at the Chairman's request, to thank Mr. Urie for the paper just read, which, to say the least of it, had been of a highly amusing character. As a Society they had often been indebted to Mr. Urie for voluntarily supplying them with an evening's instructive amusement, and he (Mr. McGhie) could personally thank that gentleman on that occasion for the readiness with which he complied with the request for a paper. Again thanking Mr. Urie for his paper, and hoping before long to have the pleasure of another, he (Mr. McGhie), before sitting down, requested to be allowed to add that he would use his utmost endeavour, as their Secretary, to do all in his power to promote the Society's welfare and interests, making their evenings as enjoyable and instructive as possible.

The CHAIRMAN expressed his opinion that the paper read by Mr. Urie was of a very humorous character, and as he had travelled over most of the ground gone over by Mr. Urie he could vouch for the accuracy of his descriptions. Mr. Urie had made reference to fishing as an art, and the pastime of celebrated artists. He (the Chairman) was of opinion that it was not so much of an art in itself as requiring a good deal of art to capture the finny tribe.

A vote of thanks to the Chairman brought the meeting to a close.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE twentieth annual meeting of this Society was held in 5, St. Andrew Square, on Wednesday evening, 5th Nov., 1879. Dr. J. A. SIDEX, the senior vice-president, occupied the chair.

The minutes of the last general and ordinary meetings were read and signed, after which five new members were unanimously elected, viz.:—Messrs. A. Clark, C.E.; Walter Forbes, M.D.; William Campbell; N. P. Spears, and William Ranken.

The following report was read by the Honorary Secretary:—
"The Council, in presenting the Twentieth Annual Report, have pleasure in congratulating the members on the Society's continued prosperity. Its members have been steadily increasing; and the fact that, during the last ten years, the membership has been nearly doubled, is ample evidence of its value and popularity.

"During the past year the Society has lost nine members by death, twenty-seven by resignation, and six by removal, total forty-two: whilst forty-seven new members have been enrolled—three of these being re-entries, and one an honorary member. The total number on the roll at present is three hundred and sixty-four.

"Twenty-five meetings have been held during the past Session—nine ordinary, one out-door, two popular, ten council and committee, one conversazione, the annual excursion, and the annual dinner.

"The ordinary meetings have been well attended, and the subjects brought under consideration have been of a practical and instructive character. The members present have invariably taken an active part in the discussions.

"The 'Popular' meetings have been popular in the widest sense of that term. They continue to be a pleasing element in the Society's operations, and it is believed that by their instrumentality the usefulness of the Society, and the increase of its membership, are to some extent due.

"Only one out-door meeting was held during the session—the place selected was 'Dalkeith Palace and Grounds.' (Comparatively little interest is taken in this enjoyable branch of the Society's work, hence this one meeting only).

"The 'Conversazione,' held on the 4th June, was undoubtedly one of the features of the past session; the apparatus

pictures, and miscellaneous articles exhibited were of an interesting and curious character, illustrating in a very striking manner the progress of photographic art from its earliest history down to the present day. Short addresses were given on this occasion by Messrs. Morton, Bow, Davies, Turnbull, and others.

"The annual excursion took place on the 24th July, and, as usual, was largely taken advantage of. It proved quite as successful as any previously got up by the Society. Almond Dell was the place selected; over one hundred tickets were sold.

"The following papers were read before the Society during the Session:—'On Art in Landscapes,' by Mr. William Neilson; 'Notes on the use of Oxygen in connection with Magic Lanterns,' illustrated by Chadwick's Safety Oxygen Generator, by Mr. J. M. Turubull; 'On the Whiskv and Water Process, a northern development of Mr. James Mudd's Gin and Water Process,' by Mr. Robert Murray, C.E.; 'The Spirit of the Journals,' by Mr. W. H. Davies; 'A New Automatic Syphon,' with a working model, described and constructed by the inventor, Dr. William Taylor; 'Notes on the use of Artificial Light in Photography,' by Dr. Drinkwater, F.C.S., &c.; 'On the Selection of Subjects from Nature suited for Photography,' by Dr. Alexander Hunter; 'On the Theory of Colour Sensation,' by Mr. Robert Bow, C.E.; 'On Failures in Carbon Printing,' by Mr. W. H. Davies.

"The following were also exhibited and explained at the ordinary meetings:—'Specimens of Dry-Plate Landscape Work,' by Mr. Robert Murray, C.E.; 'Mr. J. Thomson's Work on Cyprus, with a series of Rosetti's Views,' by Mr. W. H. Davies; 'A Series of Chinese Photographs,' by Mr. James Crighton; 'An Instantation Shutter,' by Mr. F. Bingleman; 'A Dark Slide made from Paper,' by Mr. J. M. Turnbull, &c.

"The thanks of the Society were given to the Autotype Company, and the Platinotype Company, for their interesting contributions to the Society's album; also to Mr. J. H. Fitzgibbon, editor of the *St. Louis Practical Photographer*, for examples of American Cabinet Portraits.

"It was resolved at an early period of the Session, to give a 'Presentation Print' to each member. The committee entrusted with this matter experienced considerable difficulty in finding and selecting a suitable subject; unexpected delay was the result. On application to Mr. George Bruce, of Dunse, that gentleman, in the most generous way, placed his best pictures at the Society's disposal; from these the committee selected, and the council approved of, one bearing the title 'Biding his Time.' This is now being produced in carbon by the Autotype Company, and copies will soon be distributed.

"In conclusion, it will be found from the Treasurer's Report that the financial position of the Society is healthy and satisfactory."

The Honorary Treasurer submitted his financial statement, a condensed report of which will appear in our next.

The reports were adopted, and ordered to be printed with the billet calling the December Meeting.

Office-bearers were next elected for the ensuing year.

President.—*Mr. John Lessels.

Senior Vice-President.—Lieut.-Colonel Herne.

Junior Vice-President.—Mr. James Henderson.

Honorary Secretary.—*Mr. Malcolm G. Dobbie.

Hon. Corresponding Secretary.—*Mr. W. T. Bashford.

Hon. Treasurer.—Mr. Hugh Pillans.

Hon. Lecturer.—*Mr. W. H. Davies.

Hon. Auditor.—*Mr. Alexander T. Niven, C.A.

Members of Council.—Mr. A. Craig-Christie, F.L.S., Mr. James Small, Mr. W. Douglas, Mr. F. Bingleman, Mr. G. G. Mitchell, Mr. Thomas Pringle, and Mr. Alexander Mathison.

A group picture of the Members of Council for the past year taken by Mr. Moffat, was passed round the table, and greatly admired. Mr. Milliken contributed two photographs of the Kirkcaldy Exhibition to the Society's album, and received a vote of thanks.

Votes of thanks were given to the retiring office-bearers and to the Chairman, after which the meeting adjourned.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE Annual Dinner of this Society took place in Young's Hotel, on Friday, the 7th November. Mr. LESSELS, President of the Society, occupied the chair, and was supported by Mr. Henderson (Junior Vice-President) and Dr. Sidey.

* Those with an asterisk attached to their names were re-elected.

Mr. M. G. DOBBIE, the Honorary Secretary, acted as *croupier*, and was supported by Mr. W. T. Bashford and Dr. Alexander Hunter.

The usual round of toasts, with short speeches and music, occupied the evening, which was the most enjoyable that has been held for many years.

AMATEUR PHOTOGRAPHIC ASSOCIATION.

A COUNCIL MEETING of this Society was held on the 13th inst., at 12, York Place, Portman Square, ARTHUR FARRE, Esq., M.D., F.R.S., in the chair.

The minutes of the last meeting having been read and confirmed, A. C. Swinton, Esq., and Lieut.-Col. J. H. Biggs were elected members.

The Secretary then laid before the meeting the prizes which had been awarded at the annual meeting:—A large silver goblet for R. O. Milne, Esq.; a silver goblet each for W. S. Hobson and R. Murray, Esqs.; an oil painting in frame each for J. W. Leigh, J. W. Richardson, G. G. B. Creswell, R. Loventhorp, and E. Swinbourne Esqs.; an album each, elegantly bound, for the Marchioness of Anglesy, T. R. Shervinton, Esq., and Rev. W. Hancock; a graphoscope each for F. Beasley, R. O. Milne, and T. Brownrigg, Esqs.

A vote of thanks to the Chairman, on being proposed by Mr. Glaisher, and seconded by Capt. Lewis, was passed by the meeting.

A. J. MELBUSH, Hon. Sec.

N.B.—The prizes will be on view at 12, York Place, Portman Square, during the next week.

Talk in the Studio.

RAPID GELATINE PLATES.—We have been favoured by Mr. Werge with a print from one of Swan's rapid plates, taken by Mr. C. D. Davis, the exposure being instantaneous, as secured by a Weaver drop shutter. The subject is a pigeon, which had just been preening herself; one of her white feathers, disengaged, is just floating away, and is secured with perfect definition. The feather is in flight, if the bird is not.

RAILWAY ROBBERY.—At the Cambridge Police Court yesterday, Henry Allford, photographer, of Aston, Birmingham, was brought up on remand, charged with stealing on the 8th inst., from the Great Northern Railway Station platform at Cambridge, a portmanteau containing lady's wearing apparel and jewelry to the value of £100, the property of Mrs. Skelton Cole, of Broomhill House, Sheffield. The prisoner pleaded "Guilty," and was sentenced to three months' imprisonment with hard labour.

To Correspondents.

THE YEAR-BOOK OF PHOTOGRAPHY, 1880. In order to facilitate our labours in preparing the YEAR-BOOK OF PHOTOGRAPHY for next year, we shall be greatly obliged to those of our readers who can favour us with brief practical papers on subjects arising in their experience, so that our annual may be, as it is designed, a complete record of the progress of the year, and a trustworthy practical guide for the future.

ZENO.—We are not, unfortunately, familiar with the *Football Times*, the *Bicycling Times*, or *The Theatre*, and hence we are not familiar with the portraits they contain. But we have an impression that the portraits in the last mentioned journal are produced by the Woodbury Printing Process. These are printed by the Woodbury Printing Company, 157, Great Portland Street, London, W., of whom you may obtain all particulars as to number and price. The price is very reasonable, but we cannot give you the figures.

R. F.—As a rule, about three minutes we have found a desirable time to float albumenized paper on the silver bath, but there is no fixed rule. It requires longer in winter than summer. Highly albumenized and stiff paper requires longer than thin soft paper. If the silver bath is weak, longer time is required; but judgment and experience are required in deciding. After the paper has hung a few minutes, it may, as a rule, be blotted off without injury. The paper should not be placed in contact with the negative whilst actually wet or even moist, but it should not be absolutely bone dry. Always print until the face is just a little darker than you desire it in the finished picture.

J. B. E.—The Artotype process is not, so far as we know, worked in this country; not, at least, under that name. It is a photo-collotypic process. There are various modifications of it, some of which are worked in this country; but not, we think, to the extent of which it is worth. It is most allied to photography in character. It has no resemblance to silver printing.

M. B. D.—It is difficult to say to what extent carbon is superseding silver printing. We did not make any comparative estimate of the comparative proportions of silver and carbon hung in the Exhibition, but, so far as our memory serves us, the carbons were vastly in the minority.

A BEGINNER.—Unless you have had some little experience in the use of distemper colours, you can scarcely hope to make a perfect background at the first trial; but with care you may succeed. Here are some instructions from a practical man. Stretch unbleached calico on your frame, and when neatly tacked on, proceed to colour it thus: Get 4 pounds of dry ground yellow ochre from a dry-salter, colourman, or ironmonger; 2 ounces of good glue, and 4 ounces of whiting. Soak the glue in cold water over-night, dissolve it in hot water, and pour it over the yellow ochre and whiting in a large basin; when well dissolved, put it on smooth and even with a whitewash brush, beginning at the top and working gradually down, taking care to use a light, even touch with the end of the bristles of the brush only. In this particular many fail in trying to get an even tint with distemper colour. Another thing to avoid is using the colour too thick; the consequence of this is, the background will be smeary. The proportion I have given suits my own light, but if the background is wanted to be darker, omit the whiting; if darker still, add a little finely-ground burnt umber. Yellow ochre is a nice colour to focus against, and if, by any chance, the background gets stained, it can be easily renewed, the next time of painting not requiring more than half the above proportions. Should any mishap occur, the colour can be easily renewed for a few pence; and if a landscape background is wanted, the addition of burnt umber and whiting with yellow ochre will supply any variety of tint required.

TYRO.—The "golden syrup" process of Mr. H. P. Robinson was a method of dispensing with the use of hypo whilst engaged in landscape photography. Hypo is an abomination in a field box, and Mr. Robinson used to leave the fixing of his negatives until he got home—developing, however, on the spot, and at the time of taking the view. His instructions were as follows:—When the plate has been exposed, it must be developed and intensified with iron; that is, when the developer has done its work, silver solution should be added to it, or, if too muddy, a fresh portion taken, to which silver has been added, and applied until the right intensity is gained; after which, instead of washing it, the following solution is poured over the plate, and the negative is placed in the box:—

Golden syrup	10 ounces
Water	10 "
Alcohol	6 drachms

Subsequently the syrup was washed off, and the negative was fixed and finished as usual.

PRINTER.—Borax was the agent used for securing solution of the resin in the shellac process.

BUNGLER.—Heat must not be used to hasten the drying of gelatino negatives. To secure great vigour, increase the proportion of pyrogallic acid. Excess of ammonia will induce risk of fog.

J. A. SYKES.—In our next.

G. THOMPSON.—In our next.

E. PASSINGHAM.—Many thanks.

MANCHESTER PROCEEDINGS.—Received too late for this week. In our next.

F. H.—You should have sent us an example. Do so now, and we can doubtless help you. A front light is not good.

POST TENEBRAS LUX.—We fear that the paraffin lamp would scarcely give satisfactory results. A good light is requisite. We have no means of forming a certain judgment. We should think the truth about half way between the two estimates.

HYP.—Probably turbid collodion. Try a new sample.

A YOUNG PHOTO ARTIST.—Too late for full answer this week. In our next.

J. M.—The offices of the Photographers' Benevolent Association are at 160A, Aldersgate Street, E.C.

Several correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE HYGIENE OF PHOTOGRAPHY.

THE *British Medical Journal* makes the strange statement that the hygiene of photography "has been for the first time studied with care by Dr. Zanetti." We have no desire, of course, to deprecate any study which Dr. Zanetti has made on the subject, but, on the contrary, are only too happy to learn that the aspect of photography from a sanitary point of view has received earnest consideration at his hands; but he is by no means the first who has been good enough to look after our health. Our readers will remember that more than five years ago Dr. Napias, the medical officer of the French Photographic Bénévole Society, wrote some very valuable "hints" on the subject, which were published in these columns and afterwards collected in the form of a pamphlet.* Moreover in Vienna, a study has been made of the Hygiene of Photography, and much valuable information on the subject published in Dr. Hornig's Jahrbuch, which we have had the pleasure to place before our readers. According to the *British Medical Journal*, Dr. Zanetti's opinion seems to coincide with that of Dr. Henri Napias. The principal defect in the calling of the photographer that needs medical attention is his sojourn in the dark-room among vapours of ether and alcohol. The photographer, it is true, has to do with noxious substances, some of which, like cyanide of potassium and pyrogallic acid, are of a highly dangerous character, but of these we can always beware. Not so with the fumes of alcohol and ether. If he practises the wet process—and there are very few who can get on without it—he must perforce inhale these vapours; and if the laboratory is warm and ill-ventilated, a long sojourn therein is very likely to bring with it sickness. Since photographers have taken to fit up their dark-rooms so that gelatine plates may also be developed therein, caution has indeed become necessary, for with these films the stoppage of every crack and cranny is an imperative necessity. If, then, photographers continue to coat collodion plates in rooms made tight for the gelatine process, we may expect to hear, according to Dr. Zanetti, of more sickness still in their ranks. Dr. Zanetti says that alcohol and ether vapours are heavier than atmospheric air (this is true as regards alcohol vapour, which may be set down at 1.6, but the specific gravity of ether vapour is only 0.72), and therefore they do not rise of their own accord, but hang about the operator. Only a thorough draught could dissipate such vapour, and photographers, even if they were willing to put up with the inconvenience of working in a current of air, would not like it on account of the particles which would obviously be moving about. Some amelioration of the defect might be made, thinks Dr. Zanetti, by having recourse to tubes in the lower part of the laboratory which would lead off the fumes, but better still would be a roomy laboratory in a cool and darker portion of the studio, where little necessity exists for cutting off the light, and therefore the air. Many photographers make the mistake of having their dark-rooms leading straight from the glass room, and hence, on the mere opening of the laboratory door, a stream of daylight rushes in: not only this, but the temperature of the dark-room is thereby raised, and when we bear in mind the low boiling points both of ether and alcohol, it stands to reason that a few degrees of heat makes very much difference. Ether boils at 96° Fah. (we often get this heat in midsummer), and alcohol at 173° Fah., so that you cannot be surprised at the copious vapours these liquids sometimes emit. A man subjected to the influence of such vapours for any length of time is in much the same condition as one who has been indulging in alcoholic liquors, and hence Dr. Zanetti tells us, as Dr. Napias has already

done, that photographers should be particularly abstemious in respect to spirituous beverages. Dr. Zanetti says that those who breathe such vapours suffer the following morbid symptoms. First of all, a sense of oppression is complained of, with painful constriction and itching in the throat, then nausea, giddiness, and general uneasiness supervene. Ordinarily, these symptoms do not last, and the workmen end by becoming acclimatised. It seems, however, that they only become so after having already contracted the germs of affections which sooner or later show themselves in a serious form if they continue to live in so deleterious an atmosphere. We might cite examples of photographic operators, says Dr. Zanetti, being obliged to renounce their profession, or to continue it in a new way, in order to escape from the injurious effect, especially of the vapour of ether and alcohol, which is the great danger to health without proper precautions. The beverages advisable to use in order to avoid the inconveniences of the prolonged etherization are lemonade, or natural or artificial mineral waters. To combat the loss of sleep, it is sometimes necessary to employ opiates associated, according to the advice of Dr. Zanetti, with aconite or antimony. He says he has not had any success with other hypnotics. For disorders of the stomach—such as loss of appetite, nausea, and vomiting—a bitter drink is recommended, consisting of a pint of water, two ounces of dry coffee, with three drachms each of quinine and quassia bark, the mixture to be left for some days, and filtered; and a wine-glass of it to be taken every morning. For the intense headaches frequent amongst photographers, some relief is obtained by drinking a glass of sugar-water to which a few drops of vinegar or sal-volatile are added. The most certain remedy, however, is the employment of methods which exclude the injurious substances alcohol and ether. These, according to the *British Medical Journal*, are the principal points in Dr. Zanetti's memoir, and they agree most curiously, as we said before, with the opinions expressed by Dr. Napias.

HOLIDAY PHOTOGRAPHY.

BY C. PEARSON, JUN.*

I THINK that at most of our meetings here we have our attention too much directed to one aspect of our art-science to the comparative neglect of the other. We hear many descriptions of processes, see plenty of very ingenious apparatus, and a very good show of results, consisting of prints brought for exhibition by the more considerate of our members. We also hear a great deal about the technical as well as the mechanical side of the science of photography, both of which are very useful and necessary; but we do not hear so much of the actual working out of the art in the field or otherwise. We here see results, we see also, perhaps, the apparatus used to procure those results; but of the circumstances under which they were produced, the pains taken, the various devices resorted to in order to obtain them, and perhaps, I might say, the interesting associations connected with them, we hear nothing or next to nothing. It would, I am sure, make these meetings more interesting and instructive if we did hear occasionally—and especially from our older and more experienced friends—about the practical working of their favourite processes and apparatus.

After some of our members had been over to Harwarden to photograph in that beautiful park, we did hear a little about the work done there, and if it were only recounting the difficulties met with, it was interesting. You remember we heard how this irrepressible photographer would go and plant himself and camera directly in front, or at least in the field of view, of some earlier arrival already at work on a good subject; how another, agreeing to do anything pointed out by an artist, shook his head in disgust at the first bit pointed out as being quite unworthy of his plates, much less an artist's palette; and of another who made it a point to expose only on subjects that others had found and taken,

* "Sanitary Hints to Photographers," by Dr. Henri Napias. (London, Piper and Carter. Price Twopenny.)

* Read before the Manchester Photographic Society.

Surely all our meetings, with the exhibiting and discussion of matters photographic, are with a view to obtaining the intended practical results; why, then, should we hear so little of one side and so much of the other? Let it be my excuse for reading this paper to hear a little of the other side, if only for the sake of variety.

It appears to me that amateur photographers—and it is chiefly to amateurs I address these remarks—may be divided into two distinct classes: those who practise photography as much for the sake of the manipulatory operations as the getting of photographs, as a hobby of itself, and those who only use it as a means to an end, and that end to be the obtaining transcripts of scenes and objects more readily and faithfully than can be obtained by the pencil or brush, and who care not by what means that required end be obtained so long as the result is satisfactory. Among the latter, rightly or wrongly, I am content to class myself. As my paper, however, is more immediately concerned with holiday photography, I will try to confine myself to that.

Once a year, at least, most of us who are confined to business are able to get a week or two from home, generally in the summer. Not many who have the chance of getting a change of air and scene neglect to avail themselves of such an opportunity of brushing away the "dust and cobwebs," as it has been described, of a year's work in town. It is then that to the fortunate possessor of a camera the time for action commences; and, if he be above the ordinary Southport or Blackpool type of holiday maker, he will be anxiously on the look-out for some field where more novelty and excitement may be found. I say "excitement"—not such as is produced or obtained by promenading the day long on some fashionable parade, the highest ambition being to be seen as well as to see; not the excitement of such artificial pleasure, but the enthusiasm and enjoyment produced by contemplating the grand and diversified scenes of nature, whether by land or by sea—nature which is the more beautiful the less it is improved by man. It is astonishing to those who look for it what a complete change of scene may be found almost at our doors. Within twelve miles from home I could show you mountain and river scenery for wildness and picturesqueness equal to that of Wales, but, of course, on a smaller scale.

For the last three years it has been my fortune to pass most, or part, of my summer holidays at sea—of all places, some may say, the least desirable, especially when one intends to make the camera a companion. It has always been my study to keep my apparatus as light and compact as possible, as otherwise pleasure is out of the question, and if it were to become a toil it would soon be abandoned. Accordingly I limit myself to 5 by 4 and 6½ by 3½ (stereo.) plates. The camera, with three double slides and extra front, is packed in a small, sling leather case, which, when filled, weighs six pounds. Into another similar case are fitted two double stereo. slides, a base-board, portrait lens and instantaneous cap, focussing-cloth, &c., weighing about five pounds. This case I generally get the friend I am with to throw over his shoulder. With a light folding tripod, two pounds in weight, I am complete for a good walk, climb, or whatever may be necessary, without feeling encumbered. Of course when from home for a time I carry the usual stock boxes of plates in my luggage. I may as well mention at once that as it is the results I aim at, obtained in the readiest and most reliable way possible, I usually purchase a stock of gelatine plates ready prepared, believing that at the present low prices of such plates it is the truest economy to do so, especially as they can now be had so thoroughly reliable. A few of the old-fashioned collodio-albumen plates, added for the sake of architectural and town views, complete my stock.

Thus equipped, a fine summer's afternoon in July—one of the very few we have had this year—found myself and friend on one of the quays of the Liverpool docks looking out for the steamer which was to convey us to our destination—Limerick. It was intended that it should have sailed

at three o'clock that afternoon; but, owing to the cargo being incomplete, they lost the tide, and had to wait till three o'clock next morning. As we had the afternoon on our hands the camera was at once unpacked and mounted for action; for I always believe something can be picked up on a fine day wherever you may be.

We took care first to get into the confidence of the captain and steward, the former being soon put right by my promising to take him just as he liked. In his company we took a stroll by the docks on to the fine sea wall, armed with mounted camera and sundry other apparatus. We were soon surrounded by a small crowd of the usual loungers who are always to be found in such places, and who seem to pass the whole day leaning over posts and walls, looking out to sea or talking with their friends.

After putting my portrait lens in the camera and the flap cap on it, I "spotted" two or three men adjacent who were thus engaged; so, quickly focussing by some object at about the same distance off, but in another direction, inserting the slide and withdrawing the shutter, I quickly turned the camera on the tripod screw in the direction of the group, flapped the shutter and then turned the camera round again, even before my friend knew it was done. The result was fair, though the focussing was not quite accurate enough. Next I exposed, instantaneously, a plate on a small vessel and a sailing boat passing at the time, with a fairly successful result.

After taking a few more views we returned to the vessel to look out for some place to convert into a dark room to change plates in. The captain volunteered to lend his deck cabin when he was not using it, and by covering the windows with several sheets of orange paper a capital dark room was obtained. When I could not use it, however, I had to do the best I could in my own cabin below by pinning paper over the portholes, and taking care to see that all apertures were carefully covered. As naked lights to use in a dark lantern are prohibited at night on shipboard I had to be careful to do all necessary changing by daylight.

On turning out next morning we were off Llandudno, having sailed in the night; it was, however, too hazy to see distinctly until we came to Anglesea, where we were much nearer land. As we rounded Holyhead and the Stack Light-houses the camera was brought into action, and two or three successful instantaneous photographs obtained as we passed.

It is a very exciting time just as the vessel is coming up with a headland; there are so many little matters to attend to. You are first anxious to focus right, which is generally difficult, as the distance is continually altering, and has to be allowed for; then to get the slide in right and withdraw the shutter, perhaps only to find at the critical moment that the flap cap is open. It is also a source of anxiety to know when the best point of view is to be obtained, as there is seldom time to take a second.

On leaving land, and making across the "open," plenty of amusement and scope for the camera can be obtained. If there are other passengers aboard they soon begin to suggest the desirability of their figuring on some of your plates, while you have to use all your arts to show the impracticability of such a course. I have taken photographs on the deck of a vessel when she has been rolling so much as to necessitate a person holding each leg of the tripod down to the deck, yet in the result there was no appearance of the vessel having moved any more than if it had been on land.

Even the vibration caused by the screw, which sometimes makes the vessel tremble very much, seems to have no ill effect, because both the lens, the camera, and the deck all move exactly together.

On this voyage, with the exception of a few steerage passengers and four or five stowaways who turned up in the morning, we were the only passengers, so had not much work in this way, though the sailors were glad enough to sit when they had a chance. The next morning we were going along the S.W. coast of Ireland. The scenery was very grand about Cape Clear, Dingle Bay, and Valentia, though rather

too hazy and distant for the camera, consequently the pencil had to supply its place. On waking the following morning we found that we were at anchor in a quiet corner just inside the fine estuary of the Shannon.

While patiently waiting for the breakfast bell an interesting relic of past times, though rather common here, came alongside—a canvas canoe or coracle, containing two men who had a few crabs and lobsters to sell. A lighter or frailer craft could scarcely be imagined. When both men pulled, it fairly skimmed over the water, and it took me all my time to get a plate ready and expose it before they were some distance off. A few plates were exposed as we were going up the river—one on an encampment of soldiers on the river bank.

(To be continued)

AN EXPOSING VALVE FOR RAPID PLATES.

BY M. NOTON.*

THE extraordinary sensitiveness of gelatino-bromide plates has made it desirable that a good mechanical means should be had for exposing them in the camera. Lately several designs, varying in arrangement, have been published and constructed for that purpose. There is still room for more, and another design, to be one amongst the others, is offered to you. It differs from all the others, as it opens and closes at the centre line of the lens or lenses, on the principle, partly, of the adjustable stop I published in No. 48, for 21st November, 1856, of the *Journal of the Photographic Society*.

In the *British Journal* for 8th August last, H. L. Bundy says that "a perfect shutter must open from the centre," &c. The design now before you does this, the opening being square, "as no other shape will retain its form under varying sizes. In the *British Journal*, No. 181, for January 1, 1863, you will find a delineation of an instantaneous shutter, by M. Tissot, for a stereo camera. It has square openings from the centre. There is an inconvenience in a double "shutter," as it stops any alteration in the distance between the lenses. The design before you is for one lens. The foundation plate carrying the moving parts may be of wood or metal; in this case it is supposed to be of wood, all the other parts being metal.

Fig. 1.

Fig. 1 shows the valve full open, or at half-stroke, for

* Read before the Manchester Photographic Society.

the moment. Fig. 2 is shown as having just completed an

Fig. 2.

exposure, and is now shut. Fig. 3 is a side view of fig. 2, with the addition of the front plate carrying the sun-shade or flap shutter. This shutter should be closed immediately

Fig. 3.

after an exposure has been made, to ensure against any accidental opening of the valve, before the dark slide holding the sensitive plate has been closed.

The sliding plates A and B are each separately connected by the links C and D to the circular disc or crank plate E—one at the front and the other at the back. A short axis F, upon which the disc E is fixed, and passing through the base-plate, has a pulley, G, at the other end; this pulley is put in motion by an elastic cord or spiral spring, restrained by a trigger catch—not shown, as they

are easily understood. Half a revolution of the disc gives to each of the sliding plates the stroke required for opening and then closing.

The principal moving parts being in duplicate, and moving in opposite directions, balance each other. The timing of the exposure may be adjusted by varying the tension of the elastic cord or spiral spring. Another way would be by putting in a Waterhouse stop at the back of the valve.

During the last twenty years instantaneous shutters have made very little progress—simply because there were no instantaneous plates to be had. Gelatine has altered this, and now a rapid exposur is required to meet the rapid plates; hence the various contrivances cropping up. My impression is that this exposur is the best out, and as it is free to all they may be made *ad libitum*.

“LOOKING BACK.”

BY AN OPERATOR.

CHAPTER XI.
BOHEMIANS.

“*Saluste*: I think thou knowest every ruffian in Madrid!

Cesar: You do me honour—and ’tis one that I deserve. There’s not a vagabond of all, who’s not my intimate acquaintance.”

VICTOR HUGO.

I HAD now done with the quiet business, but it had not done with me. That may sound strange, but I shall make plain my meaning presently. I had shaken off the disease, but it had left what old world people would term its “dregs.” I had been a year altogether struggling in that social man-trap for bread, for bare life; and during that period I had never been enabled to add to my wardrobe—quite the contrary—so that I found myself in a position very expressively defined by the single slang word “seedy.” Yes; there could be no doubt about it. I was seedy—I was shabby, and down at heel; brush and scrub as I would, I could not get back the brightness to the shoes, or the pile to the coat that had looked so well twelve months since. Supplement this with the two facts that I had used up the best of my specimens in the show cases of the little business, and that the fogs of November were just commencing, and you will perceive what an undesirable position I had got myself into; you will likewise perceive how it was that the quiet business had not finished with me.

“Sweet are the uses of adversity,” wrote the great dramatist; but in my case I cannot discern much sweetness in it, unless it be that my old woman and I seemed to be a bit fonder of one another than in the days of our prosperity, thus giving the lie to the old saying that when poverty comes in at the door, love flies out of the window. At the risk of being termed severely just and bitterly truthful, I must tell you one grain of worldly wisdom that I learned in those days of bread without butter, and that was, that it was not only counted a sin to be poor, but a downright crime, and that you might as lief have the smallpox or plague as an empty purse when you try to make friends.

Adversity makes you acquainted with strange companions. That is true enough, as I shall presently inform you how, through my poverty, I became thoroughly acquainted with the wandering Bohemians of our profession. I believe every trade or profession has its rear-guard of Bohemians—roving vagabonds that love free air and sunshine, whose whole existence is made up in change—now in the sunshine, now in the shade—warm in their tatters, rich in their poverty—one day revelling in a windfall of luck, and the next swaggering *a la Jingle* with a whole farthing or a brass button for their sole earthly treasure. Other businesses have their wauderers, as I said before, but I do not think you will find among them all such a jolly, light-hearted rogue as the thorough-paced photographic Bohemian. He punts the others completely in the shade; he is as full of self-conceit as a third-rate actor; he is an artist,

and will talk you stupid about light and shade; will tell you the merits and demerits of our first-class houses; will pass his opinion on the Rembrandts at the last exhibition, and he will take a ferrotype of you for sixpence! You will stumble upon him everywhere—in the country lanes—in the garden of some well known hotel—on the sands among the bathers—or on the racecourse with the book-makers. He is full of impudent wit—wit that verges on trickery. He will take a glass picture of John Hodge, put it carefully in a case, and, while pocketing the half-crown, give particular instructions that the case has not to be opened for three or four hours, as the picture will fade if it gets the light. That case burns Hodge’s hands—he cannot keep it in his pocket—he is for ever fiddling with it, and at length he can resist no longer; he opens the case to find a dim plate without the slightest vestige of a figure upon it. Hodge swears, and returns to our Bohemian, breathing warlike threats. But our artist is waiting for him—he knew how it would be, and listens to Hodge with a hurt and offended air.

“Good Gad, sir! what did I tell you?” he cries, when Hodge has finished. “Did I not tell you that if you gave it the light before it got quite dry it would *spile* it? And here you ’ave been and doue it! But as you are a decent sort of chap, I’ll tell ye what I’ll do! For another shilling I’ll do ye a regular screamer.”

Thus he obtains three-and-six for his picture.

When I write of these Bohemians I do not include those poor ragged wretches who wander the country, levying small contributions from benevolent photographers, awaking their charity by long rigmoroles about their troubles. These spiritless things are the beggars of the profession, and, a hundred to one, were never worth salt to their porridge. Your true Bohemian would scorn to beg; the spirit of adventure in his nature would tempt him to steal his dinner rather than beg it: but it is rarely he ever comes to that, for his ready brain is almost always sure to devise some means to turn the nimble shillings. London, or, as he terms it, “Smoke,” is his head-quarters; here he lies fallow during the winter months, doing odd jobs, buying and selling, or takes up a stand at some of the suburban pubs., or otherwise passing the time until the spring meetings come round, when he once more lays in his small stock of glasses and chemicals, and commences his summer roamings.

One Friday I observed an advertisement in the NEWS for a good operator—apply at a certain number in the City Road; it likewise intimated Sunday work. A year before I would have scorned such a place; but now things were changed, and bread had to be won; so breathing a silent prayer that I might be the first to apply, I started off as fast as I could walk. Quick as I was, I found no less than three before me, and as I came away I met a fourth going in. He was rather what you might call a handsome fellow—tall, with a ruddy complexion, and frank-looking eyes. His dress was somewhat stagey, and, like my own, “seedy.” He wore his hat very much on one side, and had a knowing, devil-m-care look about him that told at once he was a Bohemian. He smelt of beer and tobacco a yard off. Instinctively he knew what I had been about, so, with a grin and a familiar nod, he exclaimed: “Been after the billet?”

I said I had, and added that three others had been there.

“What! Three before you?” he exclaimed. “Well, it is hard times, and no mistake. No use of me going in.”

With that he wheeled on his heel, and walked alongside of me, whistling as carelessly as you like.

“You look down on your luck?” was his next remark.

I told him I had good reason to be so, and, tempted by that strange feeling that sometimes makes you deluge any stray acquaintance with your troubles, I told him how I

was situate. He roared with laughter when I told him about the quiet little business.

"So it was you was bit?" he exclaimed, after drying his eyes on the sleeves of his coat. "Old Jinks drew you in nicely; you *was* green, and no mistake. However, the best of us will make a mistake sometimes. Where are you off to now?"

"To Walworth. I see an operator wanted there."

When my new acquaintance heard this he went into convulsions of laughter. Seeing my vexed look he tried hard to control himself, and in broken tones told me to bless my stars that I had met with him, finishing up with the assertion that I was *green*, and no mistake.

"You come along with me," he added; "I'll introduce you to some fellows that will be able to tell you summat about the Walworth crib. Come along, it aint far—just the other side of the "Eagle."

Although I had been more than a year in London, I had failed to make any acquaintances in the profession, so that I had a wish to see what they looked like, and as we jogged along the City Road I wondered if they were all like my new acquaintance. In a short time we reached the house, and passed into a private compartment, where we found some five or six young men smoking and drinking four ale out of pewter pots. My companion was hailed by the name of Latt whenever he appeared, and a pot of beer handed to him. He evidently was a favourite among them. I was introduced as a brother, and was ordained a member of the community upon standing a pot of beer. I then had time to look around and make observations. They had all much of a sameness about them: they had the devil-me-care look and the restless eye, the shabby and mixed clothes with the cleanly paper collar; beer and tobacco was their principal perfume. Still a set of jollier dogs I never saw; with one exception they seemed to be gifted with a high sense of the ludicrous, their quips and repartee and hearty laughter being quite refreshing to hear. This exception was a sour, red-haired fellow, with bloodshot eyes, who rejoiced in the grim sobriquet of the "Assassin."

"It's supposed he killed some one, sometime," was the careless and vague explanation my friend Latt gave me when I enquired the origin of it. "He is down on his luck very bad just now," he added. "He had a nice little stand out Wood Green way, and he went in to get a half-pint, leaving his tent and camera sitting at the corner of the house. While he was smacking his lips over his beer, a young cow came along the road, and seeing the tent spread out in a provoking sort of manner, he went at it straight and played old Harry with it; not only that, but when the "Assassin" went out to expostulate with it, poker in hand, the brute doubled him up so tight that it took him a week to stretch himself up again. "Boys," he continued, addressing the others, "my young friend here was thinking of applying for the Walworth crib."

"What!" cried the lot, "Old Mother Moggs!"

Even the "Assassin" lifted his gloomy eyes and looked at me with interest when he heard this. I need not enter into details of the "crib" in question. Enough if I say it was one of the "sweating" shops where the poor operator had everything to do, and where he had a slave-driver over him in the shape of a widow with a tongue like a two-edged sword. The horrors related by these Bohemians relative to this widow would have made old Weller's hair stand on end, and redoubled his hatred to those "lone lorn creturs." One of her operators had twice attempted suicide; another had run away, and never been heard of since; while her last one was then lingering in the hospital. I resolved not to apply for that "crib."

"She once played the 'Assassin' a rum trick," quoth Latt, as he lit his pipe; "didn't she, old boy?"

An oath was that amiable creature's answer.

"Come, old fellow," continued Latt, jingling some coin

in his pocket, "I'll stand you three-penn'orth of your favourite if you tell us the whole game."

After a good deal of pressing, and after he had taken a gulp of his favourite, the "Assassin" blinked his blood-shot eyes, and spoke as follows:—"It wur a rum game and no mistake, an' one as she will 'ave to hanswer for when she goes aloft, I bet, for she 's good as robbed me of a fiver! You must know as how the house steward of Colney Hatch is related to me by marriage, and so when they has their fetes and galas he is always able to get me a free pass, and manages as how no other photographer can get in. So yer see it was always a nice little thing for me to look forward to. Well, it so happened that Moggs's young man's name was the same as mine, and by some mistake or other the free pass for the fete was sent to him instead of me. I was awfully hard up at the time, and the night before the fete, to make things sure, I went and made inquiries, when it was discovered that the steward had certainly sent a pass. Well, being well acquainted with the gate-keeper, I managed to get in all right without a pass next morning, and then the first thing I see is a camera and a young fellow working away like mad, and there was that she-devil going grinning about picking up sitters. Under the circumstances I could say nothing, but make the best of a bad job. So I opened out my traps after I had threatened to expose the artifice by which they had gained admission; and as soon as I had seen my friend the steward I made sure they would be kicked out; and in turu I looked for sitters: but the devil a one could I get—they all went to the opposition—and the visitors stood around and watched poor me as if I had been a natural curiosity. I couldn't make it out: but towards night the whole truth burst upon me. I had wheedled a young lady to sit for a glass picture, and was busily engaged in drying the picture, when a friend of hers came running up and exclaimed—

"Why, goodness gracious, you don't mean to say that you are letting him photograph you!"

"Why not?" asked the young lady.

"Why?" replied her friend, "why, because he is a lunatic!"

"The truth was out then! The mean skunks had gone and spread a report among the company that I was an inmate with a foolish partiality for photography, and consequently they carried the day, and, as I said before, tricked me out of a fiver. However, fire and brimstone awaits her yet," he added, as he drained his glass. "And now I will go and get some block ornaments for the old woman's dinner."

He left after bestowing a slow wink upon the company. I did the same shortly afterwards, and on the way home resolved never to go back, for I saw that their companionship could do me no good—in fact, quite the opposite—and, indeed, anyone might see in their society a fair opening of going straight to the devil. Still these merry vagabonds have something likeable about them, and one trait they possess, that it would be well for their more respectable brethren in the art to practise, and that is faithfulness to one another in misfortune.

And now I have come to the end of my sketches, and must write the word—

FAREWELL!

The cloud soon passed away from me. The wheel had gone to the bottom, and was bound to come up again. So take heart of grace, my unfortunate brothers, and look for the silver lining. Remember, the darkest of dark hours precedes the dawn. With resolution and perseverance man can overcome anything. And now, gentle reader, I hope these jottings have met with your approval, and let me hope that, independant of the amusement, you have learned something from them—some little grain of common sense, if nothing else, that made you think—some sentence that awoke in your breast a kindly feeling. If I have succeeded in this, my end has been accomplished. Au revoir

GEO' BRADFORD, of Bath.

COPYRIGHT.

ON another page we print a letter from Mr. Bassano upon this subject, in which he adopts and endorses the recently-expressed opinions of Mr. Brothers on the question. Mr. Brothers was good enough to tell us, in one of his letters, that he regarded our views on this subject as "entirely incorrect." As these views are regarded as possessing some authority by a large circle of readers, it is important that they should at least be based on definite ideas. Mr. Brothers maintains that the copyright of a portrait belongs "entirely to the sitter," who may have the portrait copied or enlarged, or do with it just as he pleases, without consulting the original photographer. But he further maintains that as the original photographer retains possession of the negative, he should always have the right to print from his own negatives.

Mr. Bassano, referring to our remark that "copyright exists in the design of the picture," assumes that when we used the word picture, we meant photograph. We meant precisely what we said. The word picture in its broadest sense simply means a resemblance or representation. In its more restricted or technical meaning it means an artistic representation. But for the purposes of the law of copyright it is clear that no consideration of artistic elements could be entertained. If we meant "design of the photograph," Mr. Bassano thinks that no such "mythical abstraction as design" can exist in a photographic portrait. For the purposes of his argument we will assume that we did mean "design of the photograph," and we think we shall show that his contention is altogether erroneous, and that his conclusion that photographic portraits need not be brought under the provision of the law of copyright is altogether antagonistic to the interests of the profession.

First of all it is desirable, for clearness, to define terms. It seems to be tolerably clear that a misconception of the meaning of copyright exists. We have the highest respect for Mr. Brothers and Mr. Bassano as men of intelligence and portraitists of experience; but we fear that they have scarcely thought out the question of copyright and all that it comprehends. Mr. Brothers would retain for the photographer the right to print from the negative, but give the copyright entirely to the sitter. Now copyright means the sole right to copy or issue copies, and if the sitter possessed the copyright, the photographer could possess no such right. Mr. Bassano thinks there is no design in a photographic portrait. If there were none, no action for infringement could ever be maintained, as it is the design which constitutes the identity of the picture. All photographic portraits of the same person would be precisely alike if there were no design in a photograph. The design is the very essence of a picture, and we here include photograph in the term. Design, of course, involves invention, and that we claim, too, for the photograph. The

photographer invents the pose, the arrangement of light and shade, and of accessories, in some degree the expression, and all, in fact, which makes the portrait distinctive. Mere variation of technical qualities, such as sharpness and clean photography, would make little difference between good and bad portraiture. Perception of character and of pictorial fitness, and pictorial possibilities in the sitter, and mastery over technical conditions, to bring into existence or embody those pictorial possibilities and characteristics, and so secure a picture instead of a mere map of the face or projection of the individual, constitute the portraitist as distinct from the merely mechanical photographer. Mr. Bassano, as a portraitist, has been exceptionally successful, but he will scarcely tell us that it is solely due to producing clean sharp pictures of his sitters, and nothing more! He admits, however, that to make a picture agreeable to the eye, the light and shade and line must be governed by the laws of chiaroscuro and composition, but adds that these are "fixed and learnable laws, and are not inspiration or design." Mr. Bassano opens here a very wide and important subject, not to be disposed of in a sentence. But he is probably aware that there are very high art authorities who insist that in painting a portrait the artist must produce precisely what he sees—what exists, in fact, in the model—and that therefore there is no room for design or inspiration. If it were true that the laws of composition and chiaroscuro were fixed and learnable laws, their acquisition and mastery is an important part of the education of an artist. But they are not fixed laws; that is, they are not such laws that the simple application of them would produce a picture. Mr. Bassano probably knows, as we know, some who can repeat the text of such laws with the glibness of a parrot, but who have no power whatever to produce a picture, or even a satisfactory and pictorial photograph.

There are very many good reasons why photographs should be included in a Fine Art Copyright Act, and many strong reasons why photographers of position should not suffer themselves to assume that such protection is unnecessary. It may be very unimportant whether a copyright exists or not in the portrait of Tom, Dick, or Harry, or in the thousand and one common-place portraits taken in the daily practice of the various studios. But in the practice of most photographers there comes at times an occasion when the existence of copyright in a photograph is of much importance, and unless the law comprehends all photographs, it will not protect exceptional subjects. There is a tendency ready enough on the part of those concerned in legislature to treat photography with contempt, and if portraitists of position aid them by their opinions it might easily happen that by a stroke of the pen photography might disappear from the new Act. This would be more likely than that subtle and complicated qualifications and conditions should be inserted on behalf of photography. In the new Bill, published in our columns some months ago, which it is hoped will become law in the next session of the Parliament, photography is very fairly treated. Copyright in photographs rests in the proprietor of the negative, which protects the photographer; but where a photograph is taken for a valuable consideration—that is, where it is ordered and paid for—the photographer may not sell or exhibit it without the consent of the person for whom it was taken. By this condition the public is protected from the exhibition or issue of portraits without permission, a protection which must be satisfactory to all concerned.

There are various reasons, readily appreciable from the photographer's point of view, why the copyright in a portrait should be vested in the producer. A skilful portraitist generally puts in a portrait more thought, time, and ability than are fully paid for by the guinea received for the first dozen prints from the negative. He has more than one object in producing a fine portrait: he is, of course, anxious to please, and in doing so he hopes to

secure further orders from the negative, and he has, generally, a reputation to maintain. If he possess no copyright in his work, it may be easily copied by the cheap copyists who offer to do such work at half-a-crown, or some such sum, per dozen. This is mortifying enough; but it is not all. A good portraitist almost inevitably has a style which makes his work distinctive; and in many cases we can say, unerringly, that is a Rejlander, that is a Robinson, that is a Blanchard, that is a Sarony, and so on. Probably those who are familiar with his work will say, without risk of mistake, that is a Bassano, when they see one. When, therefore, the cheap copyist reproduces these works, badly printed and rapidly fading, the original portraitist's style being recognized, he receives the discredit of the badly printed and fading print, and is thus doubly wronged, in reputation as well as pocket. It is contended that if the original photographer hold the copyright it may often put the owners of a portrait to inconvenience when they wish to have it copied or enlarged. This is rarely, we think, likely to happen, as the original portraitist, or his representatives, will generally be accessible. Or if all were defunct or *non est*, there would be none to object to the copying without permission. The projected Act promises, as we have said, to consider fairly the rights of all parties, and unless some unnecessary interference take place it is most likely to become law.

THE PHOTOGRAPHIC EXHIBITION.

THE Photographic Exhibition which has just closed was in many respects the most successful of the long series of which the Photographic Society possesses the just credit of holding. It has been successful in the number of visitors in receipts, and in the high general excellence of the works contributed; and, with very few exceptions, in the general satisfaction which has attended it and its management. In regard to the distribution of rewards, it is inevitable that some difference of opinion should exist. But the explanation given by the President at the last meeting when distributing the awards must have gone far towards neutralizing any dissatisfaction felt. The members of the jury, having individually examined every picture, and met for consultation, found that amongst them they had marked for distinction a very large number of pictures, so large, that to distribute medals to all would tend to depreciate the value of medals. On re-consideration, they found that they were absolutely unanimous in their judgments as to twelve of these meritorious works; and to these twelve it was resolved that medals should be awarded. Then came the reconsideration of the remainder, in regard to many of which they found they were only just short of being unanimous. They did not like to leave such highly meritorious works unnoted; they resolved, therefore, that they should be mentioned with honour. No idea of a fourth-rate award of "honourable mention" was intended, but simply the distinction of being mentioned with honour, as of too much merit to be passed over in silence. A celebrated judge once gave a younger man, just elevated to the bench, the advice to deliver his judgments with all firmness and decision, but to avoid giving his reasons, as whilst the first could not be successfully challenged, the second might. We think the reasons given by the President must have satisfied everyone, and materially ameliorated any dissatisfaction with the awards.

A few closing remarks are necessary on the essentially pictorial contributions to the Exhibition. There were no very ambitious attempts this year: no large composition challenging comparison with the painter's art. But there were several very clever and pleasing "subjects." Standing prominent amongst these were the pictures sent by Mr. W. Gillard, of Gloucester; pictures which we should very gladly have seen recognized by a medal, but which received the mention with honour to which we have referred. These were admirably photographed single

figures, in which pose and expression were made to tell a tale. In "Footsteps" we have the listening aspect which tells of footsteps near. "Little Bo-peep" is a charming little girl, as is also the "Little Flower Girl." Admirably managed subjects, artistic feeling, and very perfect photography are seen in every one. Mr. G. Bruce, of Dunse, also sends some very excellent *genre* studies, all of a rich, engraving-black tone, printed on collodio-chloride of silver. The "Interior of a Farrier's Shop," in which a horse is undergoing the process of being shod, is very admirable, both in pictorial composition and truth to nature. The "Little Henwife," "D'ye want a licht?" and "Dinna gar me laugh," are all excellent bits of character. Mr. A. Distin, of Fife, whose works we have before spoken highly of in these pages, sends two pictures to the Exhibition this year. One entitled—unfortunately, we think—"Henry Kirke White in his Study," is a single student figure, in a quaint interior, of the very highest merit. The pose, the expression, the light and shade, and the composition are all pictorially perfect, and much more like a copy from an Old Master in painting than a photograph. His picture of "A Washing Day" is also a fine piece of composition. "Beatrice and Rover," by Samuel Fry, is a pretty composition. Beatrice is a pretty and winsome girl, resting on a style, whilst her attendant and protector, Rover, proud of his office, crouches at her feet. The landscape is effective, and the picture pleasing. A clever study by Mr. Henry Dixon, entitled "When Doctors Disagree," consists of three birds; in the Zoological Gardens, we presume. They are pelicans, we fancy; but our natural history may be at fault. One looks ill and disconsolate, whilst the other two look wise and antagonistic, admirably justifying the fantastic title. Mr. Dixon's grand head of a lion, and his son's studies of a lion and lioness, are amongst the most effective things exhibited. Mr. H. Garrett Cocking's "Fern Seller" and "Between the Lights" are very good, but scarcely so effective in subject as some of his former contributions.

The Exhibition was not, as we have before remarked, distinguished by special novelties. The enamels by the tissue process, sent by the Autotype Company, were very effective, but the colour was scarcely pleasing. Some good enamels were sent by Mr. H. N. White, especially as judged by an admirable portrait of the late Mr. S. Phelps. The most interesting novelty was found in the examples of Mr. Willis' platinum process, many of which were of a rich neutral black, without any coldness or tint of blue. It was noteworthy that those exhibited by Mr. Willis, being presumably from suitable negatives, were very perfect indeed, whilst some others were flat, and somewhat cold. We cannot but believe, however, that, properly managed, the process has a great future before it.

FIRE ON THE AUTOTYPE COMPANY'S PREMISES.

THE premises of the Autotype Company, in Rathbone Place, on Thursday, the 20th, were the scene of a very terrible accident, issuing in a serious fire and some irreparable loss. We may say at the outset, however, that it was scarcely possible that such very serious dangers should have existed with so little actual calamity. The collapse and crash down of the large building, and immediate envelopment in fire, during business hours, at a time when nearly a score of persons were on the premises, without loss of life or personal injury to anyone, is really marvellous. Much of the immunity was due, from what we can learn, to the courageous presence of mind of Mr. Walter B. Bird, a member of the firm.

The losses, which are heavy, belong entirely, we believe, to the Company, negatives and other property entrusted to them by their customers being safe at Ealing. The Company keep up an insurance on goods entrusted to them, so that little risk to the public was involved. An

original Teniers, or copper, which was in their hands, had been sent off the day previously to Ealing; but the "Garden Party," by Desanges, was destroyed, together with some drawings by Cave Thomas, Beavis, Poynter, Lucey, Nichol, Lake Price, and L. Cattermole, all of which were the property of the Company. The books and cash box were fortunately saved, and we believe business will proceed as usual.

It seems that a few weeks previously the adjoining premises were burnt to the ground, damaging the party wall of the Autotype premises. Various surveyors representing insurance offices, the surveyor of the Company, and the surveyor of the Board of Works, had examined the premises, and their various instructions for safety carried out; but spite of all, the crash came when quite unexpected. We subjoin some details from the *Autotype Notes*:—

Things appeared safe enough whilst the claims upon the various Insurance Offices were being arranged. On Wednesday last some ominous cracking was occasionally heard, and a fissure in the party wall perceptibly increased. Our artistic staff and clerks naturally became a little anxious, and we summoned afresh a well-known architect and surveyor to report as to the safety of the building. He made a careful examination, and came to the conclusion, that while the wall would have to be rebuilt entirely, we need not alarm ourselves as to any question of immediate danger.

On Thursday morning, however, the fissure had increased, and a warning sound of a split or a crack, not loud, but unsatisfactory, was every now and then heard. The Manager posted out again for surveyors and builders, as he began to share the anxiety of his staff. At eleven o'clock he shifted every person from the upper story, thinking that the only party really dangerous. At half-past twelve, getting more dissatisfied, every person was ordered to the ground floor, and even while getting down books, easels, materials, &c., there were mysterious sounds far from reassuring. At one o'clock, the whole atmosphere seemed alarming, without anyone being able to say distinctly where the danger was. At ten minutes past one, every one was summoned to quit the building, and while in the very act of exodus, the party wall fell outwards into the chasm left by the previously burnt-out house, carrying with it three floors, and pitching all their contents into the space. Some of the people had gone to lunch, but there were some seventeen others making their escape as the building fell; only half the endangered persons escaped into the street, where nothing could be heard but the crash of the fall, or seen, but the cloud of dust raised by it.

The front stood erect, and the wholesale entrance by the side of the gallery was not blocked up. The Manager and a police inspector entered, found the side door into the gallery could be opened, and the ceciliug of the front shop had so fallen that it was possible to enter the gallery. To the first shoutings to know if any one was there, there was no response. The assistants had backed into the gallery, and were, probably, for the moment stunned by the occurrence; however, upon further calls, they answered, and the grand satisfaction was experienced of seeing every person emerge, covered with dust, from the fallen *debris*, and frightened enough, but no one seriously hurt. Neighbours, of course, opened hospitable doors to receive them, and in a few minutes reasonable composure was restored.

In these few minutes, red light and gleams began to flicker all over the *debris*, and it was soon evident that a tremendous conflagration would follow. There were comfortable fires burning at the time of the fall in at least eight of the rooms; the gas had been lighted in the gallery, as the morning was foggy; and the broken-up floors, framed pictures, partitions, and furniture, open full to the air, afforded every facility for a blaze. In twenty minutes from the fall of the wall the fire had leaped into every storey; it seized on the flooring, ran up the picture-frames, danced round the windows, and sprang with an immense blaze right through the roof. By the time the first engine arrived, the fire was a magnificent spectacle, and had, of course, its London crowd of eager sight-seers. Engine after engine arrived; abundant water was available; but the fire had obtained such a hold that there was but little chance of saving any of the property. By the time the fire in the front premises showed signs of being overcome, the flames burst out in fury in the gallery, which runs back some forty-five feet from the front shop. All the mahogany cases, with examples of classic art, all the framed pictures

which covered the walls, and the gigantic painting, "The Royal Garden Party at Chiswick," valued as 3,000 guineas, were all utterly destroyed. The partners of the Company retired from the scene of the disaster about four o'clock, whilst the engines were still pumping tons of water on the ruins; but all danger to the adjacent buildings was considered to be over.

Immediately upon the outbreak of the fire the Manager, with a fireman and one of the clerks, had again penetrated into the gallery and secured the cash box and the most important books of the Company; but all chance of salvage was limited to five short minutes, so fierce and rapid was the spread of the fire. The building and contents were, of course, insured for a reasonable amount; and although the Company must suffer very considerable inconvenience, there is every reason to hope that its customers will experience very little detriment. The injury to them will be principally a slight delay. Such of the work immediately in hand as required artistic finish was, of course, wholly destroyed; also several large orders, packed ready for delivery. Happily for the Company and their clients, Autotype production is carried on at the works at Ealing Dean. There, all the negatives are stored; and immediate attention will be given to the replacement of whatever has perished in the flames.

The Company have taken the premises No. 11, Rathbone Place, which will be their London address during the rebuilding of the offices and gallery.

FRENCH CORRESPONDENCE.

PHOTOGRAPHY ON WOOD FOR ENGRAVING—PHOTOLITHOGRAPHY—INSTRUCTION IN PHOTOGRAPHY.

Photography on Wood for Engraving.—Valuable inventions are, in some respects, the birds of passage who fly long distances to spread their lovely plumage under a less rigorous climate, but who always return to the land where they first built their nests. The application of photography to wood engraving, which is so successful in facilitating the work of the engraver, has been carried into many distant countries where conditions favourable for its practice have retained it until it has become well known. Now it returns again to France with its reputation enhanced, only it comes back again like the bird of passage, and revisits the spots where it first constructed its nest. A distinguished and indefatigable operator—M. Billon-Daguerre—has taken up this kind of work as a speciality; and at the late International Exhibition at Paris he showed some very remarkable specimens of this process, which he has brought to a great state of perfection. M. Billon-Daguerre, however, suffered on this occasion the fate of many other deserving exhibitors, for the jury did not even think him worthy of a mention. It might have been supposed that his transparent photographs on albumen, which are so highly thought of in the scientific world, would alone have earned for M. Billon-Daguerre the honour of a high distinction. This miscarriage of justice was alluded to at the time in the PHOTOGRAPHIC NEWS, and will be fresh in the memory of its readers. The great improvement introduced into the process by this able inventor consists in the substitution of silver chloride for the iodide of the same metal. By the older system of preparing the plate with this latter substance an inverted print was secured on the wood; that is to say, the blacks were white and the whites black. Thus the draughtsman or the engraver—generally the former—was compelled to work on and correct the image that had been obtained. Thanks to M. Billon-Daguerre, this defect no longer exists, and I suppose that the photographs on wood taken by this process abroad are produced under the same advantageous conditions, otherwise the bird will have returned to its nest despoiled of its plumage. In England this fact must be fully recognized, since the process has been applied there now for some years; at any rate, it must be well known, for photographs on wood have often been ordered here by your countrymen. Without being entitled to the reputation of a novelty, therefore, the process is quite worthy of the praise which is now generally bestowed on it. The bird has found its

season of song arrived, and that is all; for ourselves we have only to rejoice at it. In effect, the artist, thanks to the photographic transfer of his drawing to the wood-block which is to be placed in the hands of the engraver, has no reason to fear that its character will be altered; he will have no occasion to correct his work for the engraver, since it remains in his own possession, and may even serve as a guide and a copy. He is quite free from any chance of accident, and his original work is no longer doomed to obliteration. Formerly this work was quite destroyed by the hurin of the engraver: now it can be preserved as a precious record, and can be reproduced when the need arrives.

Public Instruction in Photography.—Though several societies have held meetings, there is no occasion to give an account of the proceedings, as they appear to have been confined to questions of management and administration. It is better to draw attention to these proceedings only when they have special interest for photographers. As a general rule, the photographic journals keep their readers *au fait* with the transactions of all these meetings, of which the number is increasing from day to day, and this, of course, is a good sign for the future. But meetings are like gardens: we need not for our own purpose gather all that grows in them. It may be of greater interest to glance at the steps which are being taken to push photography as a subject of public instruction. The *Association Polytechnique* has just issued a programme of its public courses of lectures, and among them figures one on photography. To M. Bertin, a very able professor, has been entrusted the duty of delivering this course, and his special aim will be to explain to his audience the progress of the industrial applications of photography. The *Polytechnic Association of France* was founded in 1830, and by the decree of the 30th June, 1869, received its charter of incorporation as an institution of general public utility. Since that time it appears to have attained a very flourishing position, for its courses of lectures are always attended by a numerous and attentive audience, eager to avail themselves of the instruction which is thus given for their benefit. The lectures are not only gratuitous and open to the public, but the professors who give them are honorary, though all are men of the highest position, each in his special faculty. It becomes an agreeable duty to record the efforts that are thus made to popularise photography in all quarters, but these efforts will not suffice to attain the ends of those who hope to see our art occupy a still higher rank. Photography as a subject of instruction must be made to take a definite position in the programme of studies of our schools generally—always and everywhere. It will have to be taught to our youth just the same as history or mathematics, physics or chemistry. Plying with the subject will be of no use; the taste for our art must be given simultaneously with the first rudiments of learning in our scholastic courses, in order that the youth may have it before him in his choice of a vocation, at an age when his desires for it are first formed. Then, and not till then, will he have the subject before him as an object of serious study from which he may expect to derive great results. But what is even more necessary to acquire is the artistic taste which is of so much importance in the practice of photography. We must have schools for teaching retouching, without the careful execution of which the image rendered by nature herself is liable to be ruined by every ignorant first-comer. That we shall always be compelled to retouch there is too much reason to fear, but at least let it be confined to repairing those unavoidable accidents which are easily capable of repair, and let it be carried out in accordance with the principles of true art. These principles are not difficult to be taught, but, unhappily, they are generally disregarded in our studios.

K. VERSNAEYEN.

Correspondence.

REMOVING HYPO FROM PRINTS.

SIR,—Allow me to draw your attention to Mr. Higgins' letter of the 7th October, in which he states that a solution of hypo, being of greater specific gravity than water, will naturally fall to the bottom, and remain there. Now, sir, I think it would be unnatural if it did anything of the kind; in fact, if it was natural for hypo to fall to the bottom, and remain there, Mr. Higgins could not make a solution of hypo at all. I shall have to see a better explanation of Doctor Mastermann's invention before I commence washing my silver prints in that manner. When, and how, did the Doctor invent a method which totally reverses one of Nature's unalterable laws? The diffusion of liquids (and a salt in solution is a liquid) is as certain in its operation as the diffusion of gases, and quite as beneficial in the economy of nature. Hence we have the salt in the sea diffused all through the sea, not going to the bottom and remaining there, and the carbonic acid of the atmosphere diffused all through the atmosphere, not falling to the bottom and poisoning us.

Miller gives Graham's various experiments with the laws of diffusion, and one of them proves the certainty with which salt will permeate all the water within its reach. Soda hyposulphite is placed in one of the groups of salts having a certain rate of diffusion, and it is rather a slow rate, but it is certain, so I stir my prints well up, taking advantage of the law of diffusion; change the water often; do not think the hypo is out in less than twelve hours, and not even then.—Yours respectfully,

Lindley, Huddersfield.

JOHN ALLEN SYKES.

[Our correspondent overlooks a most important factor in the case—the influence of agitation or movement. Mr. Higgin is careful to state that the vessel must not be agitated, knowing how that would aid a process of diffusion. The diffusion of gases is, as a rule, more rapid than that of liquids, but our correspondent cannot be unaware that carbonic acid does not readily diffuse itself through the atmosphere. Every well-sinker knows it accumulates and remains at the bottom of a shaft, because it is heavier than the atmosphere. In the well-known *grotto del cano* it remains at the bottom sufficient to kill any animal thrown there. In regard to fluids, let our correspondent try the following experiment. Fill a dish with a 40-grain silver solution for printing purposes, and flood a dozen or a score of sheets of paper without moving the dish. He will find the last few only imperfectly sensitized, because silver has been steadily withdrawn from the upper strata of the solution. Now let him agitate the dish to facilitate diffusion, and the next sheet will be all right. Experiment alone will determine the exact extent to which Dr. Mastermann's plan will work; but that a denser liquid will sink to the bottom of a lighter one into which it is gently introduced, and will not readily diffuse without the aid of agitation, is beyond a legitimate doubt, and may be easily proved by taking a coloured dense solution, the fall of which can be seen.—ED.]

THE PHOTOGRAPHIC EXHIBITION.

DEAR SIR,—In the current number of the NEWS, Mr. John Vaughan, of Oxford, repeats an accusation made by him in your columns of the 31st ult. against the Council of the Photographic Society of Great Britain, and charges them with "playing fast and loose" in not adhering to their published regulations as regards wall space rental. This week the accusation takes a specific form, and avers that the Society does not apply for the amounts due under this head.

In reply, I beg to remark that the assertion comes with very bad grace from one who is neither a member nor in any way a contributor to the Society's fund, but who has in former years left us to bear the burden of displaying his

exhibits in our gallery. Of course we thank him for his pictorial help, but not for sending the self-same contributions two years in succession (1876 and 1877), when the young bull "Sighting a Stranger," and "A Berkshire Farm" appeared almost irrepressible, and might have come up annually until now had not the (to him) obnoxious charge for wall space intervened to put some restraint upon such a proceeding.

Mr. Vaughan is entirely wrong in saying that the Society does not apply for these charges; we collected a considerable sum from this source last year, and, again now, the Secretary has applied for and already received much that was owing for wall space occupied in the recent Exhibition. If every one acted upon the selfish principle of demanding free accommodation in our gallery, how could the current expenses be met, or in what way could the work of the Society be carried on? We pay a high rent, and incur other heavy charges in order to display the works of foreign and British photographers in one of the finest galleries in London. The policy advocated by your correspondent is not worthy of serious criticism, and the accusation levied against the Society is quite unfounded.—I am, dear sir, yours very truly,

JOHN SPILLER, *Treasurer.*

THE SWALLOW IN FLIGHT.

SIR,—I think "Enquirer" is too much concerned about the Swallow, and must be very narrow in the gullet not to be able to swallow a little bird like that. I also think the artist (whoever he may be) will be extremely "verdant" if he enlightens "Enquirer" on the subject. What is it to him whether the swallow was got on the first negative, or put in with a second one? "Enquirer" has no more right to ask that question than the writer would have had (comparing great things with small) to ask of Mr. Turner, R.A., what body colours and glazes he used to get certain effects with. The picture is *there*, and the effect is enhanced by the dark spot—the swallow and its shadow.—Yours truly,

G. THOMPSON.

[Our correspondent somewhat misconstrues the case. It is a very legitimate subject of photographic curiosity whether the effect is that of a bird caught in its ordinary flight, or produced by some clever dodge. Mr. Gale is quite within his right in declining to say anything; but there can be no impropriety in others asking, in order to determine the question, is this nature's rendering of actual facts, or an artist's conception of them? If the effect be obtained by a dodge, all the credit belongs to the artist's skill; if it be a simple record of an actual fact, it is due to his good luck.—ED.]

PHOTOGRAPHIC VISITING CARDS.

DEAR SIR,—The *Queen's* correspondent "Etiquette" reviews an old idea. Over twenty years ago (in 1858-9) I produced "visiting card portraits" at two guineas per one hundred. The portrait was a small medallion, mounted in the ordinary lady's or gentleman's card with the name written or printed underneath. I believe I was the first to introduce that style of portrait, but there was not much demand for it, and the more popular and better paying style which soon followed crowded it out altogether. Everybody wanted cartes-de-visite; but only the few wanted and used the photographically illustrated "visiting card."—Yours truly,

J. WERGE.

COPYRIGHT.

DEAR SIR,—In your comment on Mr. Brothers' letter you remark: "Copyright exists in the design of the picture;" and I am led, by your subsequent reference to "negative" and "print," to infer that when you use the word "picture" you mean "photograph." Assuming, therefore, that you intend to say "Copyright exists in the design of the photograph," I am constrained to question whether there be any such mythical abstraction as design at all in a photo-

graphic portrait, and, therefore, whether the laws of copyright are in any way correctly applicable to it. As regards design, an artist conceives a picture, and, to carry it out, designs it; but a photographer, in taking a photographic portrait, simply takes that which is already in existence before him, and does not design the negative. Of course, to make the portrait agreeable to the eye, he will, if he be a clever photographer, see that light, shade, and line are governed by the laws of chiaroscuro and composition, but these are fixed and learnable laws, and are not inspiration or design. Therefore, as it seems to me that there is no such thing as design in a photograph (I do not now speak of those pictures which Mr. Robinson so cleverly invents), it would meet every emergency and settle every difficulty if the word "copyright" was altogether abrogated in respect to photographic portraiture. There is really no reason why photographic portraits should be brought under the operation of the Copyright Act at all. All that is wanted is that an enactment should be framed making the photographer the proprietor of the negative, and the sitter the owner of the prints purchased. If a photographer obtains permission to publish a portrait, the copyright thereof may be secured to him by registration of the negative at Stationers' Hall, and this is all that need be done.

Mr. Brothers is a photographer of high standing, and it is important to find that he also is of opinion that the points I have endeavoured to establish are such as would be beneficial to the interests of the profession. His long experience has shown him, as mine has made it patent to me, that in these social matters the law which custom creates is the most convenient, and therefore the best law to recognise and to consolidate.—I am, dear sir, yours very truly,

25, Old Bond Street, November 24th. ALEXANDER BASSANO.

[See leader.—ED.]

SHARP PRACTICES.

SIR,—Can you, or any of your readers, inform the writer of this what should be the course to follow with knaves who take the unwarrantable liberty of printing photographic mounts for cards or cabinets from a plate they may have in their possession, and, without any order at all, send, say, "one or two thousand card mounts," informing you, by letter, that they are just a sample of their present style of work, and, of course, sent on approval, without charge? Can you, I say, or anyone else, state what should be the course to adopt when the same individuals not only send, a few weeks after, a bill for the said very badly got up mounts, but threaten you with immediate law proceedings if you don't pay at once? As I am informed that many others besides myself have been so shamefully treated, and you can yourself be satisfied of it from the fact that the forms for so threatening the profession are lithographed, I beg that you will allow this to appear.

PRO BONO PUBLICO.

[The practice described by our correspondent is not only indefensible as a matter of honesty, but is also very foolish, if it be just what our correspondent describes. But he must see that his remedy is very simple. If he received a letter saying the goods were sent on approval, he has only to return them. If the letter state they are sent without charge, there can be no debt, and, therefore, we presume, no proceedings for debt. At any rate, such a letter should form a good defence.—ED.]

A PHOTOGRAPHIC CLUB.

SIR,—While the subject of a photographic club engages the attention of some of our best men, would it not be worth while, before arriving at too hasty a conclusion as to its form of membership and entrance fee, subscriptions, &c., to take into consideration that, to make it most successful, it should be made general? There might be a reading-room, a lecture-room, in which discussions, *a la* the conversation principle, with refreshments attached; a room where dinners, teas, &c.,

might be had ; a laboratory, where once a week some good man might instruct a class in chemistry and the many necessary matters connected with it and used in photography, and but little understood by all. In time, a studio also, with opportunities to attend a class for the teaching of lighting, posing, &c. ; a dark room for explanation to those who wish to learn the photographic manipulations, also the making of gelatino-bromide or other dry plates—persons forming such class to pay a certain fee—open to all amateurs and professionals—the members to pay less than the outside public. This, I think, might be made nearly self-supporting, without so large a sum as a guinea entrance fee to a guinea a year subscription. The Photographic Exhibition might also emanate from this centre ; and the club journal might be in request. To keep out members who are not members of societies photographic is like the railway companies who put all the obstacles in the way of the third-class passenger, who they admit pays them best. This rule would make each member have to join, if he had not hitherto done so, some photographic society, and not have to pay his subscription to the club only, but also to the society, making his subscription doubly heavy, so that he might be eligible for membership of the Photographic Club.

There are many photographers who have seceded from the different societies—distance, many inducements too numerous and not necessary to go into—who would like very much to join where they could meet lots of old confreres and have a friendly chat and perchance a smoke.* This is now hardly obtainable ; but the question is, how to do it, which is more than can be arrived at by yours truly,

JAMES SYRUS TULLEY.

Proceedings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

The ordinary meeting of this Society took place at the Memorial Hall, on Thursday, the 13th instant, Mr. C. ADIN, President, in the chair.

After the minutes of the previous meeting were read and confirmed, six new members were duly elected, viz., Messrs. Percy Collins, William Blackley, William Broughton, J. M. Bateman, Walter H. Tyas, and T. Thorp.

Mr. C. PEARSON, Jun., then read a paper on "Holiday Photography" (see p. 565), which was followed by a paper, illustrated by diagrams, by Mr. M. NOTON, on "An Exposing Valve for Rapid Dry Plates." (see p. 567).

Mr. A. BROTHERS said that he had seen a photograph of the spectrum produced in colours by Captain Abney.

Mr. THOS. SEFTON exhibited some prints from gelatine negatives, which were very fine photographs. He also showed some prints from collodio-albumen negatives ; and, notwithstanding that the former were very good, the latter bore the palm, and which, besides being remarkably good photographs, were excellently well-chosen and artistic pictures.

Mr. J. W. LEIGH exhibited an 11 by 9 collodio-albumen negative. The prepared plate, after being kept four months, was exposed for five minutes, and then kept for another period of four months before development. The result was a remarkably good negative, and spoke volumes in favour of the "old process." Mr. LEIGH also exhibited a printing-frame of novel description which he had made. It was simple in construction and very light.

Mr. W. WATTS exhibited several ladies' combination lockets with monograms "A. E. I." ingeniously contrived to draw out at each side, and form a "passe-partout" for photographs when not in wear. They were executed in silver and of his own design and workmanship, and very much admired for their novel character.

Mr. G. A. BROOKES exhibited a non-actinic lamp for the developing-room. The novelty in this consisted in not producing shadows, which is often the case with some non-actinic lamps. He also exhibited a retort-stand for holding the ordi-

* A substantial money award, say £50, might be given for some good invention connected with the progress of photography, determined by a committee chosen of the best and most practical men. This might be done yearly—say a £20, £30, and £50 prize, determinable by the Committee—which should be paid the person inventing it according to its merits.

nary conical oxygen retort. The stand contained a Bunsen burner, and was very complete.

Mr. W. B. WOOD then introduced a lamp with a globe of the ordinary type painted yellow.

Mr. W. J. CHADWICK, the Secretary, called the attention of the members to a photo-chroscope, the invention of Mr. Francis, of Rochester, for viewing lantern slides.

The members then retired to the adjoining room, where the Society's lime-light sciopticon was used to exhibit a series of coloured Zulu pictures, and a number of transparencies by Messrs. C. Pearson, Jun., J. W. Wade, W. G. Coote, John Chadwick, and W. J. Chadwick ; and, after the usual vote of thanks to all the gentlemen who had brought such interesting subjects before the meeting, and to the Chairman for his services, the meeting was adjourned.

EDINBURGH PHOTOGRAPHIC SOCIETY.

PHOTOGRAPHIC SOCIETY OF IRELAND.

The Annual General Meeting of this Society was held in the Queen's Institute on Wednesday, the 12th inst., Dr. J. EMERSON REYNOLDS, the President, in the chair.

The minutes of the preceding meeting having been read and confirmed, the accounts for the year were laid before the meeting, and were unanimously adopted.

Two new members were then balloted for and elected.

The PRESIDENT, in making a review of the formation and progress of the Society, considered it a matter of general congratulation that the Society had been able to bring together so many gentlemen who were all more or less interested in the art, and that its present prosperous condition was all that could be desired, considering the short time it had been in existence. He then at some length indicated the direction in which he thought it desirable to work, and where advancement and progress were more likely to be made.

A vote of thanks to the President having been unanimously passed, the meeting adjourned.

PHOTOGRAPHIC CLUB.

The first meeting of this Club was held at its Rooms, Ashley's Hotel, Covent Garden, on Wednesday last, the 18th inst. Mr. F. HOWARD was chosen Chairman.

During the business hour an interesting discussion took place on gelatine emulsion.

Four names were proposed for membership, and upon a notice served upon the Secretary in accordance with Rule 11, a Special General Meeting of the Club was called for Wednesday, the 3rd of December, after the formal business hour, to discuss the desirability of altering Rule 2, making the number of the Committee eight instead of five, as at present, and also any general business connected with the Club.

Mr. A. L. HENDERSON was nominated Chairman for next Wednesday.

We are glad to note that this movement seems likely to be a success, and will, we think, supply a want long felt. The meetings are strictly social, even the so-called formal hour being more conversational than otherwise ; and the Club will, we feel sure, do great good, affording, as it does, an opportunity for all interested in the "black art" to meet together once a week in friendly intercourse.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The Annual Meeting of this Society will be held at the Society of Arts, Adelphi, on Thursday, December 4th, at 8 p.m., when the election of officers for the ensuing year will take place. Mr. T. Bolas, F.C.S., will show and describe "An Apparatus for the Clarification of Gelatinous Solutions."

BOLTON MICROSCOPICAL SOCIETY.—At the second annual conversazione of this Society, held on the 21st inst., Mr. Bradley, of Owens College, Manchester, delivered a short, though deeply interesting, lecture on "A pool of sea water." The lecturer showed in a forcible manner the almost infinite amount of living creatures in a pool of sea water, and pointed out their peculiar organism and mode of life. Subsequently Mr. Parkinson, of the Bolton Grammar School, succeeded in obtaining, by means of the electric light, two first-class negatives of groups in the gallery of the hall.

THE "FEATHER IN FLIGHT."—Mr. C. D. Davies writes to inform us that the bird in his instantaneous picture was not a pigeon, but a Muscovy duck, or rather drake. It was styled a duck in the letter accompanying it; but to our unsophisticated eyes it looked more like a pigeon, and bearing in mind the incredulity which *gulls* and *swallows* had involved, we did not wish to pass off the latest rapid shot as a *canard*.

PHOTOGRAPHING A GROUP AT NIGHT.—We have received from Mr. Thos. Parkinson, President of the Bolton Photographic Society, a group containing apparently some hundreds of persons taken at 10.45 p.m., a feat probably unprecedented in the annals of photography. It was effected on a gelatine plate by aid of the electric light. Some further details in our next.

To Correspondents.

S. S.—We cannot state with accuracy the length of time necessary for portraiture with the magnesium light. Much depends upon the amount of light, whether ribbon or wire is burnt, whether one strand or more, whether wet plates or gelatine dry plates. A few experiments will best determine. So, also, with the position of the light and its distance from the sitter. The nearer it is the more intense will be the illumination and the shorter the exposure; but the risk of black upright shadows will be greater unless judicious reflecting arrangements are provided. A very good idea may be formed of the effect of the image on the focusing screen. And as magnesium light is very actinic, a good bright image will not require much longer exposure than one of similar brilliancy by sunlight. A suitable lamp with reflector should be used for burning the magnesium.

A YOUNG BEGINNER.—Oil-colours for colouring photographs in oil are obtained of the artists' colourman already ground in oil and preserved in metal tubes, from which a little at a time is obtained by removing the cap and pressing the tube. Raw linseed oil, turpentine, and megilp, or some similar medium, are also required for diluting the colours. The work will be easier and the result better if a good variety of colours is obtained. For flesh tints and head painting you will require white, Naples yellow, raw sienna, burnt sienna, Indian red, vermilion, pink madder, raw umber, burnt umber, ultramarine, brown madder, brown umber, ivory black, burnt carmine, cobalt, terra verte, ultramarine ash, and possibly a few others. For draperies and backgrounds you will require a few others. But we would recommend you to get Newman's Manual of Harmonious Colouring Applied to Photographs; a shilling book which will give you all details.

J. M. NESBITT.—Solution of iodide of mercury has been found by many the best intensifier of gelatine plates. The tone given may not, however, be found most agreeable for lantern transparencies; but we think it probable that the tone might be blackened by applying dilute ammonia after the mercury solution.

W. J. B.—The rich chestnut black to which you refer is often obtained with the acetate toning bath. It is most easily obtained with a toning bath of sulphocyanide of gold. But a primary condition is a brilliant intense negative which will permit very deep printing; then toning in almost any gold bath without previously washing the print will generally give the tone in question. The brilliant richness of tone when obtained often disappears on drying. To restore it, mount the prints with their faces in optical contact with the glass. This was done with many of those to which you refer.

HYP.—The spots in your negative are probably due to turbidity in the collodion. Such spots are not uncommon in a newly-mixed collodion which may not show any turbidity. Allowing the collodion to stand for a few days will often prove a cure. Adding half a grain per ounce of bromide of cadmium, shaking well, and then allowing to stand a day or two, will generally prove a cure.

IGNORAMUS.—If an error or contradiction appear in an author's book, the better plan would be to write to him for an explanation, as we could scarcely be supposed to give it. In the case in question, you will not, we think, on trying, find much practical difficulty; there are evaporation and other things to be considered. The set gelatine, after washing, &c., will contain only the bromide of silver formed, and as much water as it can hold, and will hence probably require a little water to make up two ounces.

A YOUNG PHOTOGRAPHIC ARTIST.—The mischance you describe, of the transferred collodion film cracking, may be due to two causes. It is probable that you slightly under-expose and push the development, and this will cause a tendency in the collodion film to split. And it is probable that you apply the gelatine to the canvas far too thickly and with a too thick solution. A thick solution of gelatine so applied to canvas will crack all over when it gets very dry. It should be very weak indeed—not more, we should think, than three or four grains of gelatine to an ounce of water, and to this we should add one drop of glycerine. The canvas should be very clean. Wash it with soap and warm water, scrubbing well with a hard brush; finally rinse with alcohol and then water, and see that the water flows in an even wave without showing greasy patches. With a very thin coating of gelatine and a good collodion film there ought to be no cracking. The carbon process is the best of all for canvas.

V. R. N.—We know very little of Leitch's process, and cannot say with certainty that photography is used in it. We believe that a lithographic image being produced on a plate of zinc, the plate is then etched sufficiently deep to produce a printing-block.

BROMIDE.—The proportion of each bromide required to unite with a given quantity of nitrate of silver to form bromide of silver depends on combining proportion, or equivalent. The equivalent of bromide of ammonia, for instance, is 98, and that of nitrate of silver 170. You must therefore add 98 parts of bromide of ammonium to 170 parts of nitrate of silver. The equivalent of bromide of cadmium is 136, of potassium 119, and so on. You will have no difficulty if you adopt this rule. Consult a manual of chemistry for the equivalents of various salts. 2. Bromide of silver is best soluble for photographic purposes in hyposulphites, cyanides, and ammonia; but it is soluble or partially soluble in various other solvents. It is, for instance, partially soluble in strong solutions of bromides of alkaline bases, and in a strong hot solution of chloride of ammonium, and very slightly so in a solution of carbonate or sulphate of ammonia. It is soluble in solution of protonitrate of mercury. 3. Gum-arabic is less liable to swell than gelatine, and more soluble.

Z. I. O.—We regret that our specific duties leave us no time to undertake the testing of prints for our readers. Besides, we do not know of any chemical test sufficiently certain to determine the perfect washing of a print.

W. R. (Eton.)—We do not remember any specific address to which to refer you for crucibles; but your London stock dealer will keep them or procure them for you.

POST TENEBRAS LUX.—Referring to some notes for the further satisfaction of your questions, we find that burning a piece of ordinary magnesium ribbon costs a fraction over a penny per minute. Referring to the question of producing collodion transfers by means of the triplexicon paraffin lamp, we think it worth trying. But trying is the only mode of determining the question. The chief difficulty consists in the fact that collodion images are rarely good if they require long exposure.

ROGER LAURENT.—We will try to send you some examples. You received, we presume, the carbon print sent some months ago. We shall have pleasure in receiving the article. It is desirable that we should receive the copy early, as the issue of the YEAR-BOOK does not admit of delay.

FIDO.—We have seen a studio of somewhat similar design, but we believe that it has not been so convenient and successful as was anticipated. We should prefer the glass, now proposed to form steps, in one long slope, which would give a better and less interrupted light. The chief disadvantage of iron is that it is difficult to arrange blinds and curtains, as you can drive no nail, put in no screw, and find a general want of facility for fixing anything. We do not think iron makes much difference in the heat.

J. P.—Marion and Co., of 23, Soho Square, keep the largest stock of photographs of all kinds of any establishment we know, and will, we think, best suit your purpose for a selection, especially if you make a personal visit and make known your object.

THOMAS PARKINSON.—Many thanks for interesting photograph. We shall have something to say about it in our next. Too late this week.

AN OLD FRIEND.—Thanks; but we never notice such things. If a donkey kick you, it is not wise or dignified to kick again. If you enter into personal encounter with a sweep, you inevitably get smirched. We do not profess to understand what he means.

F. H.—Your negatives were smashed to fragments from imperfect packing. We have warned readers, until we are tired, against packing glass otherwise than in a box. A print will enable us to advise you.

The Photographic News, December 5, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO. PAINTINGS AND PHOTOGRAPHS OF LANDSCAPES—THE PHOTOGRAPHIC CLUB.

Paintings and Photographs of Landscapes.—Mr. Payne Jennings is an unwise man. We are willing to admit that by issuing his landscape studies artistically coloured he has at any rate forestalled others in the matter who would of course have presented them to the public as original "water-colours;" but why did he not put the sketches forward in the first place as paintings, and not as photographs. Now, every art-critic that sees them will call out, and refer to the charming little vignettes as only coloured photographs, whereas they might have been regarded as paintings, and highly praised for their art qualities. We saw a collection of these pretty pictures in the Strand the other day, and were charmed with the delicate way in which they had been treated. There was a view of the Dargle, and another of the Lake of Killarney, to all appearances rare water-colour drawings, but having as we knew the valuable quality of being true to nature. And this quality, we are sorry to say, is seldom possessed by pictures painted for us by many who have a reputation for the work. How many times have we seen Cader Idris or Ben Lomond towering to the skies in hand sketches of this kind, and rocks rising miles high out of the water to represent the banks of a Norwegian Fjord. The last instance of this sort we remember was during the autumn at Skye, while we were stopping at the solitary inn at Schligachan. There is a detached pillar of rock near the top of one of the mountains in the vicinity, and a picture of this phenomenon, painted by an artist of repute, was shown to us one evening in the smoking-room. It was a most weird example of a natural pillar, and of such gigantic dimensions that our party did not hesitate about paying a visit to the spot the next morning. The affair, as might have been expected, turned out but a traveller's tale, and the rock we were shown turned out to be not nearly so big or so wonderful as we had seen a few days before in the vicinity of Little Broom Loch. Afterwards our acquaintance admitted the painting was somewhat "idealised," and if this word means the same as gross exaggeration he was perfectly right. Now in Mr. Payne Jennings' productions we not only have pretty pictures, but we have truth as well, at any rate in all the main features, and they would at once satisfy the traveller as a souvenir, while at the same time, they would not provoke deep disappointment if visitors went to the spots depicted. But Mr. Payne Jennings, though he may have a large sale for such sketches—and we sincerely hope that he may—must not expect to obtain credit as an artist from such work. It was but a mere accident, he will be told, that he set down his camera beside the many lovely spots he has depicted, and it was the quality of the chemicals he used, and not himself at all, that brought out those beautiful contrasts, and fine combinations of light and shade. Mr. Robinson, of Tunbridge Wells, sometime ago managed to secure a "successful bit," which was never admired as a photograph, but as soon as it appeared as a painting in the Dudley Gallery (copied down to every leaf and stone) it provoked warm praise. Mr. Blanchard can tell similar tales. Not long ago, one of the most successful portraits in the Royal Academy, was, to all intents and purposes, a photograph by Mr. Blanchard, which had been coloured. But in neither of these cases did the public or art critic know that the pictures were simple transcripts of photographs, otherwise, we may be sure, there would have been little praise bestowed. It is for this reason we have said Mr. Payne Jennings is an unwise man. Of course, it is possible to stop a painter from using your work, by bringing an action at law, a remedy to which the late Mr. O. G. Reglander frequently alluded with irony, but photographers for many reasons, besides that of cost, prefer to let matters slide. The last instance of an

appeal to a court of law, we believe, was the Maidstone case, in which, our readers will remember, a photograph of Old Maidstone Bridge had been copied with striking fidelity by a painter. The photographer went so far as to prove that the bridge could not recently have been viewed from the same point of view, as the base upon which the camera had rested had since been removed. In this case the judge decided in favour of the photographer, but it is very seldom, as we have said, that photographers feel it to their interest to take such matters into court.

The Photographic Club.—We are glad to see that the Photographic Club has become a fact and has begun its sittings. There is no doubt that there is plenty of room for a social gathering of this kind beyond the meetings of photographic societies. Our friends in Germany combine the two. In Berlin and other cities in Germany where photographic meetings are held, these partake of sociability in the highest degree, and smoking and beer drinking goes on during the reading of a paper and its discussion afterwards. Probably this state of things would hardly be in accord with the British mind, but in the Great Fatherland, where beer is an institution, it would be hard to get on without pipe or glass. No doubt one of the principal laws of the new club will be that "smoking is strictly enforced," and as the first hour is to be occupied with technical conversation, the meetings will have much in common with German Photographic Societies. Here everybody chooses his own company—or, rather, group—round a small table, calls for his beer and enjoys a cigar. The Photographic Club, we see, meets at Ashley's Hotel, Covent Garden, where we have spent many a pleasant evening among the *Savages* and the *Scribblers*, when those bodies frequented the hospitable walls. And from these bodies the Club might take one hint, which is, not to have too strict rules nor too many of them. Again, members, especially at the outset of a club, should consider that they owe something to the club in return for an agreeable evening, and that, beyond going to the club to pass a pleasant hour, they should consider it something of a duty to do so, for the purpose of "making a house." Anybody can found a club or start one; all that need be done is for one of a party to say "Let's be a club," and for the others to reply "Let's," and the thing is done. But to nurse a club, and make a success of it, depends not upon one or two, but upon many, who make up their minds to assist time after time, until the affair is firmly established. We have no doubt there are men connected with the Photographic Club who can and will make it a successful gathering, and for ourselves we think there is plenty of room for such a party. So far as we know, the Solar Club is the only body of the character as yet in existence, and this is but a dining club that meets but once a month, and only in the winter months. The Photographic Club—we hope the Committee will pardon us in saying—if it is to number many members, should be upon as broad a basis as possible, so as to admit amateurs as well as professionals, and not only photographers but those belonging to kindred arts. Many a man is the backbone, from his social qualities, of a club, who has not strictly a *locus standi* therein; and as a social club, to exist, must perforce be made up of pleasant people, it is never well to be governed by very strict laws as to the qualifications of candidates.

HOLIDAY PHOTOGRAPHY.

BY C. PEARSON, JUN.*

THE city of Limerick has not many attractions artistically being for the most part poorly built and lying on the flat. There is some very fine scenery, however, in the vicinity well worth visiting. The ancient town of Galway next attracted our attention, and it would have amply repaid a more prolonged stay. It is more like a continental town—Spanish

* Continued from p. 567.

it is compared to—than anything I have seen. We had to content ourselves with a glance, and then pass on.

A small paddle steamer took us to the head of Lough Corrib—an immense inland sea thirty-five miles long, flat, bleak, and wild at the lower end, but mountainous and well wooded at the upper. The grand Connemara mountains are to be seen from the village of Cong, where we got off and spent the night. But I am straying too much from my subject—photography—which had up to this time been rather neglected, more because of the bad weather than anything else. It was amusing to see the crowds of bare-footed and bare-headed children, backed up by a few of the older sort, that turned out and followed when one chanced to leave the hotel with a mounted camera on the shoulder, and to hear the mysterious suggestions that some made as to one's object. What little I did at this village I was mainly able to do owing to the extremely short exposures requisite, as we only arrived at five o'clock in the afternoon and had to leave at seven next morning by mail car. We could have very profitably spent a week here had we been able to spare the time. Noon next day found us in the picturesque town of Westport, which stands at the head of the magnificent Clew Bay. Here again the rapid plates stood in good stead; for, after walking through Lord Sligo's demesne, which borders on the bay, commanding fine views of the district, and open to the public at all times, we were hurrying back to catch the last train out at two o'clock, when we were stopped by the gate-keeper, who informed us that photography was not allowed in the grounds, and that he would not have permitted apparatus to go in, but that we had deceived him by having them packed in cases. It did not trouble us very much, however, as we had got what we wanted, and had no time to lose, having only about six minutes left to catch the train half a mile off. Nevertheless a street view tempted me to try a plate on it, which I did with no more delay than thirty seconds from stopping to going on again. The consequence was that we nearly missed our train, but consoled ourselves with the fact of possessing a photograph of one of the streets of this town in the far west.

From Ballina, which is uninteresting, the mail car took us next day to Sligo—a distance of thirty-seven miles. The later part of the ride was very grand. Richly-coloured hills above on the right and sloping down to the blue Sligo Bay on the left, with the mountains of Donegal beyond, formed a panorama not soon to be forgotten, my regret being that I could not get a still more permanent and visible record of it.

In the vicinity of Sligo is Lough Gill, equal to Killarney and of a very similar character, well wooded, surrounding hills, and studded with numerous picturesque islands. The camera was frequently employed during the limited time we had there at our disposal. In fact, all the journey from Limerick to Sligo was more or less hurried, and was merely undertaken to catch a steamer for Liverpool, *via* the North of Ireland, and at the same time to endeavour to see as much of this comparatively unfrequented district as possible.

On the return voyage from Sligo we had plenty of company, not to mention cattle, &c. The captain was a jolly fellow, who soon made one feel at home. All were very curious to see the apparatus, and solicitous in helping with anything, so that I soon had a comfortable dark-room fitted up in my cabin below, though it required all one's care in changing, as there was a good sea on most of the time. It is a much more difficult matter than anyone would suppose who has had no experience to carefully change and number, pack or unpack, dry plates in semi-darkness, with the vessel rolling and pitching continually. Add to this the suggestive odour usually found in such places, and you are generally anxious to shorten your stay below as much as possible, and get out into the fresh air. As usual the captain figured among the first subjects my camera set its "eye" on. A rather stiff and formal-looking group—made up of a few of the hardier passengers who had not gone below for a hook and forgotten to return, and who were all arranged looking intently out to sea—formed a subject for a stereoscopic view,

which came out fairly well. Among other photographs I took one of a lady who seemed a little troubled with the *mal de mer*. An old Irishwoman was setting knitting on deck; on, however, bringing my camera near her to take her, but under the pretence of taking a view of the land we were passing, she moved away, guessing what I wanted, thus depriving me of a good picture. Many such incidents as these happen on a voyage, and help very much to relieve the tedium. I remember on a previous occasion, when at sea, a newly-married couple on their honeymoon were spied one fine, warm day resting on the fore-castle, with an umbrella over them, when I was called up and, amidst bursts of laughter, succeeded in getting a photograph of them without their knowing anything about it.

The north coast of Ireland was very fine, equal to the south, but, as a rule, was too distant for the purposes of photography. I succeeded in getting, instantaneously, a faint resemblance of the glorious sunset we had that evening, for the camera can never do justice to such scenes. On looking at it, poor as it is, how vividly it recalls the various circumstances connected with the taking of it! The mild, clear evening when waiting to take it, after tea, we were all on deck in a group round the captain, listening intently to the yarns he was spinning of adventures he had passed through—some on the very coast we were then off. I was at the same time watching a bank of clouds rising which at the time obscured the sun, and from which I wanted it to emerge before taking the view.

I always think that associations and reminiscences such as these, attaching themselves to different scenes, add tenfold to the value one sets on them, and infinitely increases the charms of photography. I could add much more about different experiences and adventures encountered on this and other trips, but I have already engaged your attention too long, and it would be needless, as I have only given the above outline to illustrate one of the many ways in which to spend a summer holiday pleasantly. Some, and I dare say many, would prefer to remain on land, and getting to some quiet and picturesque spot settle down to regular and more methodical work. I would, however, suggest that under whatever conditions we are working, original style of work be attempted, especially in these days of rapid plates. They place in the hands of the photographer quite a new power, which is only just beginning to be appreciated.

Photography in the future will not be so much confined to set landscapes as in the past. The photographer will shoulder his apparatus, which will be light and handy, and passing along will perhaps notice a group of children playing on the village green, and secure an instantaneous picture of them before they are aware; or, taking a view of the cottages, will include a passing cart and horse, with a few rustics about—not standing stock still, staring, as is usually the case at present, but in their natural attitudes. He will also secure agricultural and cattle scenes in their entire naturalness. What will prevent him from taking a landscape with cloud shadows on it, and with the actual clouds casting the shadow embraced in the picture? He will not need to drive some sheep from a particular place he happens to be taking, fearing they will be moving all the time. He will be able to take the ripples and reflections in water with fidelity, and a waterfall will not be represented like so much cotton-wool, but in all its crispness and sparkle. Why should photographs not be taken on a fine out-hazy day? Atmosphere lends additional charms to a picture. We may now hope to see a revival of, to my mind, the most interesting and beautiful form of photography, the stereoscopic transparency, which is far too much neglected at present. Let us try and work up to the examples set by the late Mr. Brees, endeavouring to produce directly what he obtained by a series of clever combinations. Above everything, let us avoid the production of stiff, though technically perfect, photographs, which seem to be taken more to show the quality or capability of the process than to obtain the great desideratum—a real picture.

ON GELATINO-BROMIDE OF SILVER.

BY DR. VAN MONCKHOVEN.*

The Dark Room.—One of the most important points to be attended to in the gelatino-bromide process is the proper equipment and arrangement of the dark room, and the most stringent precautions must be taken to render it perfectly proof against the penetration of actinic light. As, however, some light must be admitted in order to distinguish objects, there must be a window having an opening of about a square metre, at the height of an ordinary table, and glazed with a couple of panes of ruby glass, superposed one over the other with a thin sheet of white paper between them. The operating table must be placed immediately in front of the window, and be covered with a slab of black marble perfectly level and horizontal. In order to prevent any light from entering through chinks in the door, the latter should be hung with a black curtain, and the whole of the interior of the room should be painted a dead black. Examine the dark room well; shut yourself up in it for a quarter of an hour, and stop the least hole that you may see admitting light. For testing whether window is completely proof against actinic light, take a sensitive plate, and place it in a dark slide; then half open the shutter of the latter, and expose the slide close to the ruby-coloured glass window; leave it there a quarter of an hour, and develop. If a dark line appear on the plate, the colour of the glass panes is not deep enough, and a third must be placed in contact with the other two. All the slides and cameras should be examined in the same way. As slides generally allow some light to filter in at the joints, always cover them with a black cloth when removing them from the dark room, or fogged plates will be the inevitable result. In the open air, photography with gelatino-bromide is very difficult, owing to the imperfection of all ordinary photographic apparatus.

The Nature of the Emulsion.—When a solution of ammonium bromide in water is poured gradually into one of silver nitrate, so as to have the latter always in excess, there is thrown down a heavy curdy precipitate of silver bromide, which, by stirring at the bottom of the vessel, may be made easily to reunite with larger masses. If, before mixing with the ammonium bromide, a little sulphuric or other acid be added to the nitrate of silver solution, the precipitate formed is heavy, and reunites of itself; but if, instead of the acid, we use ammonia, a light white-coloured precipitate is produced, which remains suspended in the liquid. Now when gelatinous, in place of aqueous, solutions are employed, the very opposite of this happens. Take a ten per cent. solution of gelatine in water, and add to it a few drops of ammonium bromide; then shake the solution, and again add a few drops of silver nitrate. Notwithstanding the presence of silver bromide, the solution remains transparent, and if a little of the liquid be flowed over a glass plate it preserves its transparency. But if the solution be allowed to rest for a day the particles of silver bromide, which at first are in a finely divided condition, will reunite, and the liquid will turn milky. The addition of a little sulphuric acid will make the liquid remain transparent for a much longer time, but a few drops of ammonia promote the coalescence of the particles, and the liquid at once assumes the opaque condition.

The method of preparing an emulsion of silver bromide in gelatine is perfectly well known. To a solution of gelatine and ammonium bromide and gelatine in warm water is added one of silver nitrate, when white silver bromide is formed in the interior of the liquid. The more gelatine there is in proportion to the quantity of silver bromide, the whiter and finer will the latter be. Now if the emulsion be allowed to rest for a few days in a warm place, it will ripen—that is, it will become sensitive to light, at

the same time that the white colour passes into a green. Examined with a magnifying glass, scarcely any grains of silver bromide will be seen in the emulsion when freshly made; but when ripened, coarse grains may be perceived even with a single lens, especially on the edges of a plate where the films thin out. Experience has shown that the greener an emulsion is, the more sensitive is it to light. Emulsification, therefore, has the object of converting bromide of silver in its white and finely-divided condition into one where its colour is green and its particles much coarser, but where its sensitiveness to light is much greater.

Preparation of Gelatino-Bromide Emulsion.—Take exactly 10 grammes of Nelsou's No. 1 photographic gelatine and 8 grammes of pure dry ammonium; put the two together in a flask, and pour over them 250 cub. centim. of distilled water. In about a quarter-of-an-hour the gelatine will have swelled up, and on placing the flask in warm water, the two substances will dissolve. Meanwhile weigh out 12 grammes of silver nitrate, and dissolve it in 50 cub. centim. of water; then pour the latter solution by small portions at a time into that of gelatine, shaking the mixture vigorously every time that fresh silver solution is added. When the whole has been poured in, add 5 cub. cents. of pure solution of ammonia, density 0.910, and shake the mixture again thoroughly. The ammonia has the effect of making the emulsion ready for use *at once*—or, where great sensitiveness is required, in twenty-four hours—thus avoiding the necessity of waiting several days to allow the emulsion to ripen; it also prevents the gelatinic from decomposing. Now pour the emulsion into a porcelain dish, and place the latter in a pan of cold water, in order that the gelatine may set. So soon as that has happened, remove it from the dish, put it into a bag of coarse linen cloth, and squeeze it through the interstices of the cloth by wringing the neck of the bag. Let the shreds fall into a large vessel full of cold water, and wash them well; washing for about six hours in water, renewed three times during that period, will be quite sufficient. Collect the shreds of emulsion on a sieve, and melt it at a temperature of 35° C., and it is ready for use.

Coating the Plates.—Before coating them the glass plates must be perfectly clean. In winter they should be slightly warmed to enable the emulsion to flow freely; but in summer this is not necessary. The emulsion is raised to a temperature of 40° C., to render it perfectly liquid, and it is then poured into a glass funnel lightly stopped with cotton wool, which acts as a filter. To deprive the cotton of the adherent fatty matter, which would repel the liquid and not allow it to filter, it must be boiled for half-an-hour in a one per cent. solution of caustic soda, and its fibres then separated by hand. The emulsion is kept warm during filtering by placing the funnel of glass inside a double one of metal filled with hot water. Let the lower extremity of the glass funnel touch the bottom of the jar or beaker into which the emulsion is filtered, so as to avoid the formation of bubbles.

Having placed the plate in a perfectly horizontal position, and resting on three pieces of wood, pour a quantity of the emulsion (in the proportion of about ten cub. centim. for a quarter-plate) on the centre of it, and with a glass spatula spread the liquid over the whole plate in an even film; to do this properly requires practice, but the necessary facility will be easily acquired by those who have to work with wet collodion. Never pour back any superfluous emulsion into the beaker, or all subsequent films will be full of bubbles. Lay the plate thus coated on the marble table to set, and while that is being accomplished a second and a third plate may also be coated. When the emulsion is set, place the plates in a drying-box, arranged in such a way that a current of warm dry air may pass above and below each one. This operation of coating the plates must be carried on continuously until the whole supply of emul-

* Abstract of a lecture delivered at a meeting of the Photographic Society of Belgium.

sion is used up, for if the liquid be kept warm for a long time, or if it be allowed to solidify and be then again melted, the gelatine loses its property of setting, especially in hot weather, and the films spring off the plate when being developed. During the whole of the operation the plates must be kept strictly in the dark; no light must be allowed to enter the room where it is being conducted, except that which passes through the ruby panes.

Preserving the Dry Plates.—The plates coated with emulsion must not be exposed to the air, but must be wrapped each in an envelope (like that of a letter) of black paper. Or four plates separated by a folded Bristol board may be placed in such an envelope, and three of these envelopes in a cardboard box. All the plates must be kept in a dry place, or they will spoil and give foggy pictures.

Exposure in the Camera.—This operation, so simple in the collodion process, presents very great difficulties in the case of gelatine emulsions, on account of the excessive sensitiveness of the plates. In the first place it is almost impossible to meet with a dark slide which shuts so closely as to be perfectly light-proof; more especially the grooves in which the shutter slides are defective, and admit light. To prove this, place a sensitive plate in the slide, and expose it in the camera, but do not uncap the objective; it will generally be found, on developing the plate, that it is veiled all over. The camera itself must also be carefully examined to see that no light penetrates by the slits in which the stop slides, or by the ring which carries the objective. Generally—and especially when working in the open air—the best way is to cover the whole of the camera completely with a closely-woven linen cloth of a black colour. Only the opening of the objective should be left free, and the cloth drawn closely round it. Even the dark slide should be open under the cloth. Without these precautions, nine times out of ten the images will be fogged.

(To be continued).

ON RETOUCHERS AND RETOUCHING.

REFERRING to an article in a contemporary in which it is remarked that it is generally *de rigueur* to assume that retouching is an evil, even if not an unmitigated one; and the wielders of the stump, pencil, and brush are generally spoken of by their employers as negative spoilers, who ruin the plates which have cost the operator so much trouble, besides eating up a large slice of his profits, *Design and Work* has the following remarks:—

“There are retouchers and retouchers. There is the operator who is his own retoucher, and who neither knows nor cares anything about drawing. There are also the retouchers who are not operators, but who have been trained for their own department, and who do not spoil the plates which pass through their hands.

“Some ten years ago, when retouching was first introduced from the Continent, the supply of retouchers was mostly drawn from the schools of art, and they were generally selected from among those students who had considerable facility in shading from the antique, both by hatching and stippling. Of special training, they had only to add the study of the anatomy of the head (in the case of many this was not an addition, having formed a part of their artistic training, and taking the shape of studies in chalk and charcoal in addition to lists of Latin names, which are soon forgotten), some practice on the negative film, and a slight practical acquaintance with the photographic process, so as to understand how a negative is produced, and to be able to judge of how the retouching would affect the print.

“At first only the best negatives were retouched, and a special charge was made for modelling; but gradually the retouchers gained greatly in rapidity of working, and the desire of the public to be smoothed increased until such a thing as an unretouched portrait is scarcely sent

out except at the special desire of the sitter. (In Canada it is, I believe, the custom to send out unretouched, untouched, and unmounted specimens.) It was also found that all sorts of blemishes could be removed from the plate by the retoucher if the requisite amount of labour were bestowed upon it, and he was henceforth expected to turn any sort of a negative into a beautiful picture.

“About this time operators began to be careless about dirty backgrounds, pinholes, spots, streaks, rests showing, and so on. What did they matter? The retoucher could take them all out! And what was the use of trying to get a fully-exposed plate of a child? Children are always so restless! And here were two or three under-exposed plates, which, with a little extra labour, the retoucher could, nay must, turn into something presentable, else what was he there for? With groups it was the same thing; they were under-exposed, or else they were under-developed to such an extent that nothing but freckles seemed visible, and it was almost impossible to get rid of them.

“Then, again, the operator has a mania for trying new ‘wrinkles’ in the way of varnish, in the search for some method which will give him or his assistant less trouble, paying no regard to the fact that it takes some time to adapt the hand to a different film, and that the retoucher can neither work so well nor so rapidly when a hard surface which breaks the points alternates with what appears to be an entirely unprotected film, which requires to be hardened, and being then perhaps too hard, has to be softened again, entailing a great loss of time as well as temper. A matt varnish is succeeded by a glossy varnish rubbed down by the finger; then follow, in succession, water varnish, gum water, spirit varnish, softened with spirit or turpentine, or rubbed down with cuttlefish, when the round begins again.

“Then in course of time operators, who could not retouch a negative to save their lives, having seen the operation performed every day for years, begin to think they know all about it, and to lay down the law as to what is to be done. They have ideas on the subject of high lights, and have read somewhere that the high lights on the nose and forehead *may* be heightened, and that lights *may* be put in the eyes. This ‘*may*’ they interpret to mean ‘*must*,’ and high lights they will have, even if they should put them in themselves where in nature there is a deep shadow, saying, in answer to a remonstrance, while pricking at the eyes with a pin—‘Oh! come now! draw it mild; anybody can put in high lights and prick the eyes! You don’t need to know how to draw to be able to do that!’

“Then the public has learnt, or thinks it has learnt, that anything can be done by retouching. So Mr. A. requests that he be made to look at least twenty years younger, and insists on having every line of wrinkles removed. Mr. B. is quite bald, but he would like a little hair on the top of his head. Mr. C.’s nose is decidedly ‘*tip-tilted*,’ but the lady he is going to send his photograph to is somebody who has not seen him for a long time, and he would like it to be good, so would Mr. S. kindly tell his retoucher to give that feature a Roman cast? Mr. D.’s hair stands up like a brush—couldn’t it be sleeked down? Mr. E.’s moustache is not quite so flourishing as he could wish it to be. Mr. F. has a beard of three days’ growth, which he has not been at the pains to remove (that task being reserved for the retoucher), and he ‘*can’t abide*’ freckles; so, of course, the developer has been so sparingly used that they are perfectly transparent, being about the size of a drop of rain, and as numerous as stars. Mr. G. has the mark of a deep cut across his cheek, and a deep perpendicular hollow. Miss H.’s mouth is very small—very small indeed—not in the least like that immense one you have given her. ‘Oh! fie! you naughty man! what have your retouchers been about?’ Mrs. I. so much admires that lovely photograph of Mrs. Langtry, and would like to be taken just like that. She is not at all pleased with her

last sitting; she has seen the proof, which makes her much too old, quite stout, and none of her friends like it. Even this last the retoucher is expected to remedy.

"To remonstrate, and say that to remove characteristic lines, and to introduce in their stead billiard-ball-like roundity, is not art, is of no avail with people like these, who do not care for art, but wish to be improved (?); and as they are customers, Mr. S. says to his retoucher, you must just humour them—art or no art!

"For the operator, when speaking to the customer, to blame the retoucher, justly or unjustly, for every want of success with an—'Oh! yes! I assure you, Mrs. K., it was a capital negative, but the retoucher has spoilt it'—is merely a way (perhaps a natural if not a justifiable one) of diverting that worthy dame's wrath from himself, and will not hurt the other man, who does not come in contact with the siter at all, but sits at his desk 'chewing the cud of sweet and bitter reflection,' from time to time looking through his magnifying glass, and thereby probably enlarging his grievances as well as his work.

"It is useless to demand that an ill-lighted and ill-posed picture be turned into a work of art, and at the same time that attention should be paid to all the crotchets of customers—that perfect roundity should be produced, and that all should be combined with rapidity of work—because the things are incompatible with one another. In order to secure the best return for his money, the photographer should get his operator and assistants to pay attention to a few points hereafter enumerated, and then try to persuade his public to *put up* with having their portraits treated in a legitimate manner—namely, simply having freckles and accidental marks removed and exaggerations slightly softened; no meddling with the eyes, in ordinary cases, no reckless introduction of high lights where none could possibly exist, nor changing of pugnoses into Roman, and weather-beaten skins into satin.

"It is a matter of course that in connection with posing and lighting the operator will do the best he can, and that when things do not turn out satisfactorily, it is the duty of the retoucher to do his utmost to set matters right. As regards an occasional under-exposed or under-developed plate, he will probably be quite willing to do his best with them also; but when plates coming under one or other of these denominations demand from one-fourth to one-fifth of a day's work, it is not wonderful if his patience be overstrained, and the result of the last plates give evidence of hurried work. It is hardly necessary to say that when there are duplicates the best negatives should be sent to the retoucher at first, and not after he has wasted time in trying to patch up an inferior one.

"Having secured a properly-trained retoucher, do not make him waste his time and undergo the drudgery of varnishing and revarnishing, or spotting and retouching streaky, pinhole backgrounds, which could be done as well by some less highly-paid member of the staff, if it could not be dispensed with altogether by providing clean backgrounds. Then let the prints be carefully spotted, as there are often marks which it takes less time to spot out in a dozen prints than it would to remove carefully and entirely by puncturing from the plate.

"Do not always be interrupting the retoucher, or inquiring: 'Is that negative not done yet?'—as that is a sure way of causing the work to be hurried, and thus by no means improve its quality.

"With regard to the retouching medium: in choosing a preparation for a retouching surface, other things being equal, give the preference to that on which the retoucher can produce his best work most rapidly. And, lastly, let the final varnish be put on smoothly and free from dust.

"There is absolutely nothing new in these remarks; yet, though some readers may regard them as platitudes, in many other cases, if they were carried into practice, we should hear less about 'negative spoilers.'"

THE EFFECT OF SUNLIGHT UPON HYDROGEN PEROXIDE.

BY ARTHUR DOWNES, M.D., AND T. P. BLUNT, M.A.*

WE believe that it has not been previously observed that hydrogen peroxide in solution is decomposed by sunlight; it may therefore be of interest to state that during the continuation of our investigations on the chemical effects of sunlight, we found that (1) after about ten months insolation aqueous solutions, containing about 8 per cent. of hydrogen peroxide, were entirely destroyed, and that (2) corresponding solutions shielded from light proved much more stable than is commonly supposed. We are inclined to think that the insolation needs to be prolonged—although we have made no direct observations on this point—because some of the solution, exposed in a thick glass bottle standing in a window, was found to be still of considerable strength after a period sufficient to destroy a corresponding sample in a thin test-tube.

We have elsewhere shown that oxalic acid is destroyed by sunlight by the oxidation of its hydrogen by external oxygen, thus:—

There is not, we believe, any analogy whatever between that case and this. There we have the "chlorous radicle" C_2O_4 in combination with the basylous H_2 , the latter being seized upon by the superior affinity of the external oxygen stimulated under sunlight. Here we may regard the hydrogen peroxide as made up of two atomic groupings of the chlorous radicle HIO and, if the theory we suggest be correct, the decomposition in this case is brought about by the dissociation of these radicles. We believe that the tendency of sunlight is to dissociate (or "waken the internal bonds" between) what we have termed "chlorous radicles," whether these be simple, as oxygen or chlorine, or compound, as HO , and thus to promote their combining energy, or to bring about a more stable arrangement of their constituent atoms.

A NEW STEREOTYPE COMPOSITION.

A composition which may be found useful by experimentalists in photo-engraving is given by the *Scientific American*. This is known as Jannin's cement, from the name of the patentee, a resident of Paris. The cement is simply a mixture, in suitable proportions, of yellow oxide of lead (the quality known as massicot being preferable) with glycerine. Several other metallic oxides and matters may be mixed with the cement, so as to suit the quality or the colour of the cement to the nature of the work to be produced, but the two essential compounds are yellow oxide of lead and glycerine. The proportions of oxide of lead and glycerine vary according to the consistency of the cement it is desired to produce. The proportion of glycerine will of course be larger for a very soft cement than for a stiff cement; it is not necessary, therefore, to specify the exact proportion of each of the two essential compounds.

This cement is especially adapted for moulding those objects which require an extreme delicacy in the lines of the cast, such as engraved blocks and plates, forms of printing type, photoglyptic plates, &c. Under the influence of gentle heat it sets in a few minutes, and then resists perfectly both pressure and heat. When set, it is also a very good substitute for natural lithographic stones, and it can replace them for many practical purposes. It can also be used for artistic reproductions, such as *facsimiles* of terra-cotta, whose colour and sonorous quality it possesses. Though setting to great hardness in a few minutes, it does not shrink. Massicot, it may be observed, is an old name for litharge, but the term is more generally applied to the yellow oxide of lead, prepared from the scum of the molten metal by roasting until the colour is fully developed. For purposes in which the colour is of no moment, the scum itself would doubtless answer, provided it is thoroughly oxidized.

A PHOTOGRAPHIC CLUB.

ENGLISHMEN are said to be essentially clubbable men; insular and unapproachable to those whom he knows not, he likes to form one of a circle or coterie of common tastes to whom he is known. But the circle or coterie must have its bond of union, each member must recognize the privilege of belonging to it, inaccessible to all outside. It is not simply a society with a common business aim, or scientific object, it must, as a rule, involve a social element. The members have generally the facility of eating together, drinking together, and entering more or less into social relations.

Photographers have from the commencement of their art-science manifested something of the gregarious element, meeting together to discuss the new wonders they were daily making acquaintance with, but have not manifested much of the social tendency. Their ardour has been chiefly scientific, rarely inducing them to break bread with one another. Many years ago, a few choice spirits, members of the Photographic Society, formed a Photographic Society Club of a social character, the members of which dined together on specific occasions, talked of their experiences, and exchanged trophies. The death of some of the members, and the subsidence of zeal on the part of others, was followed by the dissolution of the club some sixteen or seventeen years ago. Partly from its ashes, sprang into existence, very shortly afterwards, another club, entitled the *Solar Club*, a society of gentlemen in *lux* way. This has continued in successful existence, the members dining together at regular intervals during the session of the Photographic Society. The fact that the number of members is limited to something like five-and-twenty indicates, what is undoubtedly the fact, that this is a somewhat select and exclusive coterie. But there has been no general aggregation amongst photographers other than that found in the various societies.

An effort has recently been made, however, to alter this. The South London Society has always been distinguished by enthusiasm and by social tendencies. It is the only society in London in which the members dine together once a year, and they are entertained once every year at the house of their genial president; and some of the members have resolved to form a Photographic Club for social intercourse amongst photographers and all interested in photography, for there appears to be no restriction in the rules as to eligibility for membership. All candidates duly proposed, whether they be professional or amateur photographers, or in any way interested in photography or photographers, it appears are eligible for the ballot for membership. At one time it was contemplated that membership of some photographic society should be a necessary pre-requisite for candidature. That, we think, would have been an unwise limit. There is not necessarily any connection nor antagonism between membership of a society and membership of a social club.

The rules which are before us are simple, and relate chiefly to the necessary regulations of any organization. There is one rule of the working of which we are doubtful. An hour is to be devoted each evening to technical discussion, under the presidency of a chairman. This, we fear, will be found inimical to the social character of club meetings. That conversational discussion of technical matters will arise amongst a number of gentlemen with a common subject at heart is quite certain; but it is a question whether it might not be more pleasant arising and being conducted in an informal conversational manner, than when provided for by the formal machinery of a business meeting.

There are already two photographic meetings held every month solely for the discussion of technical matters, at which, however, discussion often flags. It is true that during the past summer a series of improvised weekly meetings were held at the establishment of a London photographer, without the machinery of a society, and at these meetings, as the president of the South London Society remarked with surprise, the discussions were lively and brisk. But this was, we apprehend, chiefly due to the somewhat informal character of the meetings, and partly the fact that, being freed from the formal arrangements of a society meeting, the proceedings were not necessarily formally reported in the journals. It is true that in all probability the club technical discussions will be somewhat free and easy in their nature. In some of the Continental photographic societies, the ordinary meetings are free enough from restraint, tobacco and beer being the usual accompaniments to scientific discussion; and, so far as we can judge, the discussions do not suffer in interest or precision as the consequence of this social practice, whilst it must at times materially relieve the tedium of a long dry paper of little practical interest. The club technical discussions will probably partake somewhat of this character. Regarding technical discussions, let them remember it is possible to have "somewhat too much of this!"

The aim is one which we think should meet with general approval, and much depends on the management as to whether it becomes a great success or dwindles into an unimportant clique. All are eligible, in country as well as town, country members only paying half the amount of subscription. The club-room, we may add, is central, being in Henrietta Street, Covent Garden, and we may also add that the Secretary is Mr. G. C. Cutchey, of Loughton, Essex.

NIGHT PHOTOGRAPHY.

WE briefly mentioned in our last a marvellous feat in photography, one beyond question unparalleled in the annals of the art. It consists in the production of a group of upwards of one hundred figures in the gallery of a large hall within an hour and a quarter of midnight. The photograph is excellent, sufficiently well defined to justify the intention of having it enlarged. The photographer is an amateur, but evidently one of great enterprise and ability. To Mr. T. Parkinson, the President of the Bolton Society, and Principal of the Grammar School at Bolton, belongs the credit of pioneer in this new phase of photography.

The scene was the Albert Hall, Bolton, and the occasion a conversazione of the Bolton Microscopical Society. A couple of electric lamps swung in front of the group; one light, worked with a Siemen's machine, gave a light equal to three thousand candles: the other was a Gramme machine, the light equal to six thousand candles. The first lamp was placed at about forty feet from the group, and the other about seventy feet. One of Wratten and Wainwright's instantaneous gelatine plates was used, and with a Dallmeyer's cabinet portrait lens, and a stop one inch and a half in diameter, an exposure of forty-five seconds was sufficient to give a well-exposed negative, when developed with alkaline pyrogallol acid,

The attempt was a bold one, and the success complete. What variety of memorial groups will follow we cannot anticipate, now that Mr. Parkinson has shown the way. For the detailed operation we have not space at present, but we hope to give Mr. Parkinson's own account of the matter in the forthcoming YEAR-BOOK OF PHOTOGRAPHY. We may here, however, indicate what appears to us an important point in the arrangements. The two lamps were placed at different distances in front of the group. That nearest would give the greatest vigour, whilst that at a great distance would give a more diffused light, and greater softness. Hence the group is free from the harshness of light and shadow which is generally associated with the electric light, and artificial lights generally.

Since writing the above remarks we learn that other plates were exposed. One of Cussons and Co.'s extra rapid gelatine plates was exposed for thirty seconds, with a pair of Dallmeyer's patent stereo lenses, and yielded an excellent negative, prints from which will be issued with Mr. Cussons' little pocket almanac shortly to be published. The stereoscopic negative was produced by Mr. W. Shipperbottom.

FRENCH CORRESPONDENCE.

LECTURES ON PHOTOGRAPHY IN FRANCE AND IN ENGLAND.

In the number of the PHOTOGRAPHIC NEWS for the 21st of November last, a valued contributor, speaking of the lectures on photography which are about to be delivered in Paris by M. Davanne and by myself, expresses a fear that a long time will have to elapse before courses of the same kind will be instituted in London at the charge of a spontaneous grant from the English Government. We on this side of the Channel are certainly rejoiced that our enterprise meets with favour among our friends on the other side, and we should be still further honoured if our example were thought worthy of imitation. For my own part I expressed an opinion only that as the photographic art is much more popularized in England than here, lectures of the kind indicated were less likely to be valued than they will probably be in France. It is not that I consider it useless anywhere to organise a course of lectures on a science which is able to render so many and great services, nor yet that I refuse to approve a project for enlisting in its behalf the action either of a public department, or, in default of that, of any photographic society which would properly direct its energies in that direction.

The author of the paragraph to which I have been alluding maintains, with perfect reason, that photographic chemistry and photographic physics constitute of themselves complete faculties, calling for a distinct system of instruction quite apart from that usually given in ordinary physics and chemistry. Such a statement is quite true. In the year 1863—a period which many will consider merits the epithet of "long ago"—I gave a series of lectures at Marseilles before the Faculty of Science in illustration of a photographic exhibition that was held there at the time. The Dean of the Faculty, the lamented M. Morren, was kind enough to afford me all necessary facilities for arranging the course, and gave me his valuable assistance in preparing the lectures; but even now I can recal the astonishment with which he marked the reactions of light on numerous substances previously quite unfamiliar to him. He had, in fact, in the course of a long and brilliant scientific career, never had his attention called to these special results, and the phenomena were to him quite unexpected. Photography is, in truth, a science of itself; those who seek to study it, whether they be already advanced in scientific attainments, or young beginners, or even professional photographers, have all to acquire a special kind of information on the nature of the operations that they have to carry out, in order that they may understand the theory of the physical and chemical facts that present

themselves. The progress of photography must necessarily become more rapid when those who practise it as a profession bring their every-day experience to bear in aid, so to speak, of the researches of the theorists, who often fail in the practical details of the science.

To return, however, to the subject we were discussing, after a digression which has already been extended to too great length, let me draw attention to the circumstance that the course of six lectures to be given by M. Davanne at the Sorbonne is organised by the Scientific Association of France, and will probably be attended by the same class of persons as would attend a similar course in London. Quoting the words of the introduction to the published programme of this course:—"It is a subject of regret that there does not exist in France a central institution, like the one that has now been established in Belgium for more than ten years, where anyone who feels an interest in learning and following the general photographic processes can with facility and convenience acquire the necessary information. The Council of the Scientific Association of France, presided over by M. Milne-Edwards, and the President of the Photographic Society of France, M. Peligot, have together arrived at the conclusion that this want might, to a certain extent, be met by the organisation of a course of lectures bearing on the general principles of photography. The principal object of these lectures will be to make known, both by oral teaching and by experimental demonstration, all those photographic processes that up to the present can only be studied by means of works in which the special branches are treated. A considerable part of the course will be devoted to the elements of the subject and to those several photographic processes a knowledge of which is necessary for the different applications of photography. The lectures will be more especially addressed not only to artists and to scientific men, but also to amateurs and to those professional photographers who desire to complete their practical knowledge by a more extended study of the reactions which come before them in their daily work." These few words will suffice to describe concisely the nature of the instruction which our esteemed colleague, M. Davanne, has undertaken. There is no doubt that the object he has in view will be fully attained, for he knows thoroughly all that he says, and he carries out completely all that he takes up.

Here, then, we have one of the sides of the question whose requirements are completely satisfied; but it has other aspects, and it is one of these that has been taken into consideration, when the course of lectures, in which photography will also have a considerable part, was arranged at the National School of Decorative Art. This course, the profession of which has been entrusted to me, will, it is intended, comprise all the methods of reproducing works of art for industrial purposes, as well as the means of treating original works of art with the object of copying them. It is not, therefore, specially a course of lectures on photography itself, but one in which it will certainly occupy a prominent place, since photography is incontestably the most faithful, the quickest, and the most economical means of reproducing original works.

Perhaps I may be allowed to enter a little into detail, so as to make quite clear the distinction between my lectures and those of my colleague, M. Davanne. He will take the elements of the art as applied to the operations that the photographer is required to carry out; I, on the other hand, have to describe only one of the objects, though perhaps the most important object, of the applications of that art. They form, therefore, two perfectly distinct systems of instruction, both having photography for their base, though it will be easily seen that there is quite sufficient subject matter for other analogous courses, completing the two which have been organized in France, and yet not clashing with them.

Knowing what we are doing in Paris, our professional brethren in England will be able to cite our example as a

precedent, and thus to overcome with greater ease the obstacles presented by the doubts and hesitation of others. For this reason, as well as in order to afford subject matter for reflection, I have thought it right to devote the whole of this letter to the question. All we who practise the art of photography belong to a noble international brotherhood; for my own part, I am as ready to do all in my power to further the interests of our art in England, as I am eager and willing to promote them in my own country.

LEON VIDAL.

HELIOGRAPHY, OR PHOTOGRAPHY IN THE PRINTING PRESS.

BY JOHN CARBUTT.*

THE Secretary having desired me to describe to the members of the Franklin Institute how photographs in printing-ink are made; before doing so permit me to read from an article prepared by me a short time since for one of our journals—"The Photographic Rays of Light."

In 1796 Alois Senefelder, of Munich, a musician and composer, was in the habit of using pieces of slate of limestone, on which to arrange his compositions before putting them on paper.

While so engaged he wrote with pencil, on a piece of this stone, a memorandum for his mother. Accidentally it fell into a vessel containing greasy water; to his astonishment he saw that every letter had become coated with grease contained in the water, and without affecting the other parts of the stone. This simple accident led him to the discovery of lithography, and little did he dream at that time of the marvellous results now obtained through the means of his invention, or that a chemically prepared surface would be discovered on which, by the action of light, natural objects, portraits, and works of design and construction would be drawn, which, when placed in the printing press, would yield, by a process of printing strictly analogous to his own, copies of such objects in permanent pigments.

In 1839 Mungo Ponton, of England, discovered that when paper coated with a solution of bichromate of potassium, and after drying was exposed to light under a drawing, that it received an image, of a brown colour, to preserve which it was only necessary to wash the paper in water to remove the bichromate not acted upon by the light. This, as far as known, is the first instance of a picture having been produced by the action of light on a body impregnated with a bichromate salt.

In 1854 Paul Pretsch made known his discovery that a film of gelatine and bichromate of potassium, after exposure under a drawing or other design to light, and after damping with water, would receive ink from a roller passed over its surface where the light had acted upon it, and refuse it where the light had not acted, owing to those parts having absorbed water, thus producing a printing surface strictly analogous to the drawing made by Senefelder on the lithographic stone; but Pretsch only used these inkable images to obtain a transfer to be laid down on stone to be printed from.

In 1855 Louis Poitevin made further advance in the use of a bichromatized gelatine film, by producing pictures in half-tone, but nothing of a really practical nature was accomplished by him at that time, as the films would bear but few impressions to be taken from them.

In 1865 Tessie du Motay, of Metz, France, made still further progress in half-tone printing from a gelatine surface, making use of copper plates as a support for the gelatine film, and from which seventy to eighty impressions could be obtained. The results were considered so good at that time that soon other experimenters took up the subject. Notably to Albert, and Obernetter, of Munich; Rye, of Denmark; Gemoser, of Berlin; Despaqui, of Paris; and Edwards, of London, is due great credit for the perfection to which heliography, light-drawing on a bichromized gelatine surface, has been brought.

* Read before the Franklin Institute.

Before describing the making of and printing from a heliograph plate I will briefly explain the similarity between a drawing by hand on a lithograph stone and a drawing by light on a bichromatized gelatine film.

To produce a design upon stone the artist makes use of a crayon or ink composed of materials of a fatty nature, on completion of which, if the stone is sponged with water, it will be seen that the water recedes from that portion covered by the design, but is readily absorbed by the stone outside of the design. On passing over it a roller charged with lithographic ink it will be seen to deposit on the drawing, but not on that part of the stone yet moist from the water, the greasy nature of the drawing attracting the ink, while the water repels it.

If a bichromatized gelatine film be exposed to light under a negative the result will be an image or drawing of a brown colour; on placing the plate supporting this film in water it will be seen that where the light has had full action, so as to reduce all the bichromate, it refuses to absorb water, and where the light has not acted it absorbs water freely and swells up. On blotting off the surplus water, and passing over it a roller charged with lithographic ink, it will be seen to deposit on the parts acted on by light, but refuses to deposit on the parts that have absorbed water, thus establishing the relation analogous to a drawing on stone as regard its acceptance or rejection of a greasy ink when in a moist condition. This is the relation produced by Pretsch's discovery in 1854, who, like Senefelder, never dreamt of the wonderful results now being daily accomplished by the aid of the camera and printing press. The drawing produced by light, first through the aid of the camera, and then by the negative thus obtained on the bichromatized gelatine plate, has a far greater intrinsic value than a drawing produced by the hand of man, be it ever so skilfully executed; for what can exceed the faithfulness with which photography pictures everything placed before the camera? Is not the drawing executed by nature's self?

Heliography—"sun-drawing"—then, is a process by which a picture is produced by light on a chemically prepared surface, from which, by mechanical means, prints in permanent ink can be produced with a celerity and cheapness, delicacy of texture, exquisite gradation, and faithful rendering of detail, that when limited numbers are required will give heliographic productions the preference over other processes of the sister arts.

I will now describe to you how the gelatine printing surface is produced. The support for the gelatine may be of zinc, copper, stone or glass: the latter, being best adapted to the purpose, is most generally used. To secure the gelatine film to the glass, so as to allow of a large number of impressions being pulled, it was found necessary to first coat the glass with a thin substratum of gelatine, albumen, and bichromate of potassium; albumen and bichromate; or albumen and silicate of soda. One or other of these preparations is essential to the production of a good printing plate; all are patented, and the patents for these and other improvements are owned by a company in New York known as the Artotype Company, who grant licences for working them. I hold the exclusive right for photo-mechanical printing for Philadelphia and twenty-five miles radius.

If one of the first two formulas for a first or cement coating is used, the plate after drying is placed, face down, on a board covered with a black cloth or velvet, and the light allowed to act through the glass for a time sufficient to cause that side of the coating next the glass to have become insoluble; it is then carefully coated with a solution of fine gelatine, containing fifteen to twenty per cent. of bichromate of potassium or ammonium, placed in a drying box, which is a rectangular one having cross bars, supplied with screws, on which the glass plates have previously been brought to an accurate level; and dried at a temperature varying from 110° to 130° Fah. When dry, the plate is ready for exposure under a negative; the usual printing-frame used by photographers is made use of, but as we cannot examine the

progress of the light's action as in photograph printing, the back of the printing frame is dispensed with, the plate being held in close contact with the negative by wedges placed under the cross bars, and we examine the progress of printing through the back of the plate. When all the detail of the image is visible, the plate is removed from the printing frame and placed in cold water, which dissolves out the bichromate not reduced by light. When sufficiently freed of the now useless bichromate it is allowed to dry. Before putting it on the press the plate is placed for a few minutes in a pan of water. It is then freed from water on the hack, placed on the bed of a lithograph press, the surface carefully sponged, and dried with a soft cloth or other means. At this stage a faint image only is visible, and on passing over it a roller charged with a stiff ink those parts answering to the transparent parts in the negative will take ink with considerable freedom, while those parts answering to the half-shades will take much less, and where no light has acted will refuse ink entirely, from the film having so freely in those parts absorbed water. The printer now takes a roller similar in composition to those used in type printing, and charges it with the same or in coloured ink, but reduced in stiffness with oil or thin varnish, and with very little on the roller. Passing this roller over the plate it continues the inking up of the image until the faintest detail is made visible. A mask of paper having an opening of the size of the subject on the plate is laid over it, a piece of fine paper laid on, the tympan lowered, and with a light pressure pulled through the press, when, if all the conditions have been properly carried out, a print possessing all the delicacy of a fine photograph, but in a pigment as durable as that of the engravings of old, and with all the minuteness of detail and delicacy of light and shade that photography so faithfully gives us.

Heliographic printing is applicable to any kind of subject that can be photographed, and for publishers and manufacturers offers the best means of producing portraits, landscapes, machinery, and all kinds of manufactures; reproduction of engravings, paintings and original drawings, old manuscripts, &c.; and for illustrating art and manufacturers' catalogues.

Artotypes are executed in any of the permanent printer's inks, and at much less cost than photographs. To produce the best results special negatives are required to produce the printing plate, and care and skill are required of the printer.

HOULGRAVE'S GELATINE EMULSION.*

ONE of our most enthusiastic emulsion workers is Mr. George H. Johnson, Bridgeport, Conn., who, at this writing, is in the Adirondack woods, with camera and gun, making all the captures he can, health included. He took with him a new American Optical Company's 5 by 8 dry-plate camera, which he calls "the prettiest I ever saw." We hope to hear from him on his return. Meanwhile we publish the following for the use of emulsion workers.

In a recent letter to Mr. Johnson, Mr. Houlgrave, of Liverpool, England, gives further details in respect to the preparation of his gelatine emulsion as follows:

"In the first place let me explain that I always prepare my emulsion and plates in the evening, so that the times for performing the various operations are calculated for this. I employ the following utensils: two German glass beakers, one holding about four ounces, the other about half that quantity; an eight-ounce bottle with cork-lined stopper (glass stoppers are apt to stick); a tin canister with loose fitting lid, large enough to hold the bottle; a flat porcelain dish, seven inches by five inches; a tin tray about one and a half inches deep, and a little larger than the dish; an earthenware vessel with cover holding from six to eight quarts; a Bunsen burner, and a small spirit-lamp. I use Nelson's No. 1 photographic gelatine, as it does not require long soaking in cold water before it is ready to dissolve.

"It is quite essential that the bromide salts should be in excess, and for this reason I always test my materials before using them. Should this, however, be inconvenient, I should advise the use of rather less silver than I have prescribed in my formula; say 45 grains instead of 46 grains. In the larger beaker dissolve 26 grains bromide of ammonium in 7 drachms of water and 1 drachm of beer, and then add 10 grains of gelatine, pressing it under the fluid with a glass rod. Place the remaining 16 grains of gelatine in a separate vessel, and fill up with cold water. In the small beaker dissolve 45 grains nitrate of silver in 4 drachms of distilled water, and add three or four drops of dilute nitric acid (this is not necessary, but it helps greatly to keep the shadows clear).

"The beer above mentioned is prepared by mixing three ounces of ordinary bitter ale with one ounce of alcohol. This lasts a long time, and is always ready to use. The nitric acid solution is prepared by mixing one drachm of strong nitric acid with one ounce of water.

"Arrange the tin tray on any suitable support over the Bunsen burner; pour on water until it is about half an inch deep; place in the tray the eight-ounce bottle and the two beakers, and light the gas. Let the temperature rise to about 100° Fahrenheit, and then lower the flame. As soon as the gelatine in the beaker containing the ammonium and the beer is completely dissolved, pour into the same in one continuous stream the silver solution, at the same time stirring briskly with the glass rod. Transfer the emulsion just made to the eight-ounce bottle, rinse both beakers with a drachm of water, pouring it from one to the other, and finally into the bottle, and then give the emulsion a thoroughly good shaking. Next place the eight-ounce bottle containing the emulsion into the tin canister, into which a little hot water has been previously poured, loosen the bottle cork, and gradually raise the water in the canister to a boil over the gas-burner (this should not require more than five minutes). Remove the light when the temperature of the emulsion has sunk to 100° Fab., add the remainder of the gelatine, having first drained off as much of the water as possible, shake gently, and keep the emulsion at a moderate heat for a short time longer, in order to allow time for any froth which may have been formed to subside; then pour the emulsion into the flat porcelain dish to set, place this on any level surface perfectly excluded from light, and leave it till the next morning. Then fill the earthenware vessel with cold water, and plunge into the same the flat porcelain dish containing emulsion, and cover up, letting it remain in a cool place till any convenient time in the evening, changing the water once an hour or so before using the emulsion.

"When ready to coat the plates, take a strip of tin or brass half an inch wide and bend it into the form of the letter V; place it in the tin tray; fill the latter with water enough to cover the brass strip, and place in the tin tray the porcelain dish containing the emulsion; heat the water with a lamp until the temperature is not less than 100° Fab.; now drop in ten drops of the chrome-alum and glycerine mixture, filter the emulsion through a piece of fine sponge into a beaker, having a mark at two ounces, and should the quantity fall short of this, make up with warm water. Next coat the plates, and place them on a perfectly level shelf, and not disturb them until quite dry.

"The beaker containing the emulsion should be kept in warm water while coating the plates.

"Development.—The ordinary well-known alkaline development succeeds with these plates very well, and for portraits it is the one which I use; but for landscapes I very much prefer the following, for which the below-mentioned solutions will be required.

"No. 1.—Put four ounces of good carbonate of ammonium into a pint bottle, and fill up with water (this will take a day or more to dissolve).

"No. 2.—Pyrogallie acid 60 grains
Alcohol 1 ounce

* *Photographic Times*.

"No. 3.—Strong liquid ammonia	...	1 drachm
Bromide of ammonia	...	5 grains
Water	...	1 ounce
"No. 4.—Alcohol	...	2 ounces
Water	...	1 pint

"Pour sufficient of No. 4. into a dish, plunge the plate to be developed into it, and let it remain there a minute or longer. Then mix the developer in the following proportions:

"One drachm No. 1; two drachms No. 4; six drops No. 2. Pour this quickly on and off the plate a few times, and then add more pyrogallic acid solution. This should bring out the image in all its details; if it does not do so, drop in from five to ten drops of liquor ammonia (No. 3). This will probably be sufficient; if not, rinse the plate with a small quantity of alcohol and mix a fresh developer, viz.:

Pyrogallic acid solution	...	5 drops
Liquor ammonia	...	2 "
Dilute alcohol	...	1 drachm

"Pour this on and off the plate, and add more liquor ammonia if required. Fix in moderately strong hyposulphite of soda (hypo, four ounces; water, one pint).

"Plates prepared and developed in this way are slow, the exposure with an ordinary landscape lens being from ten to thirty seconds; they are, however, extremely easy to prepare, are almost absolutely certain, and give the best results I have been able to obtain by the gelatine process.

"H. HOULORAVE."

Formula referred to in above is as follow:

Gelatine	...	26 grains
Bromide of ammonium	...	26 "
Nitrate of silver	...	46 "
Water	...	2 ounces

Chrome-alum Mixture.—Dissolve twenty grains of chrome-alum in one ounce of water, and then add half an ounce of glycerina.

INSTANTANEOUS PICTURES OF ATHLETIC EXERCISES.

THE San Francisco *Chronicle* has the following:—"On Thursday, at the invitation of Leland Stanford, W. S. Lawton, superintendent of the Olympic Club; Louis Gerichton, teacher of boxing; L. Brandt, the strong man of the club, and several other athletes, visited Menlo Park, Governor Stanford's country place, for the purpose of having their photographs taken while performing various athletic feats. The experiment was entirely satisfactory, the photographs being taken by the process so successfully employed in reproducing in the same manner the movements of running and trotting horses. In order to display as completely as possible the movements of the muscles, the athletes wore only brief trunks while performing. Mr. Muybridge, the photographer, had every arrangement made at the race-track for carrying out the work, and from ten o'clock in the morning until four o'clock in the afternoon boxing, wrestling, fencing, jumping, and tumbling followed in quick succession, and all of their intricate movements were instantaneously and exactly pictured. The first experiment was in photographing Mr. Lawton while turning a back somersault. He stood in front of the camera motionless, and at a signal sprang in the air, turned backwards, and in a second was again in his original position, and in his very tracks. Short as was the time consumed in making the turn, fourteen negatives were clearly taken, showing him in as many different positions. The eye cannot follow the rapid motions of a man turning a somersault, nothing but a gracefully revolving figure being presented; but the various positions assumed, as faithfully portrayed by the lightning-like movements of this new system of photography, show an amusing succession of positions which should cause a revolution in the matter of circus-hill printing. Mr. Brandt furnished a good study of muscular development for a sculptor, in putting at arm's

length over his head a dumb-bell weighing 150 pounds. Brandt possesses an arm, shoulder, and chest of a Hercules, and from the instant he grasped the bell at his feet until he held it motionless over his head, fourteen negatives were taken, showing what muscles are called into use, and how and when exerted. Mr. Gerichton and one of his pupils did some good boxing, and their rapid leads, parries, feints, counters, head tricks, and knee movements, were all caught and held by the photographer's instrument for the benefit of students of the manly art. One of the most interesting experiments was a running high jump made by Mr. Lawton. The jumping-gauge was placed at the four-foot notch, in order to give an easy jump, as in making it fourteen stout hempen strings had to be broken, as in photographing trotting-horses. From the camera to a point beyond the line on which the jump was made, a number of strings were stretched. The two base lines were only a few inches above the ground, and from them to the apex the strings were placed an equal distance apart. In jumping, Mr. Lawton's legs broke seven of the strings in ascending and seven in descending. The strings were tightly drawn, and so connected with the camera that as each one parted a negative was produced. After the athletic performance several photographs were taken of the athletes in various classic groupings. Governor Stanford will have each negative worked up to a cabinet-size photograph, and take one of each with him to Europe, where he will have two life-size oil-paintings made of each, one set of which he will present to the Olympic Club. A number of fast runners, members of the club, will visit Menlo Park soon, and be photographed at full speed."

Correspondence.

COPYRIGHT.

DEAR SIR,—I regret not having an opportunity to reply at length to the several points in your leader of Friday last, with which you have associated my name. I must, however, refer to two of them, and, with your permission, say that from a lengthened experience I have come to the conclusion that it would conduce more to the interest of photographers if clients were legally to possess the power to have a photograph for which they have paid a valuable consideration enlarged or painted by other than the original photographer. I think custom has shown this arrangement to be both necessary and desirable, and therefore that which has been found convenient and beneficial under the *lex non scripta* should now be consolidated.

The other point I would refer to is as to design in the ordinary photographic portrait. There are certain firms—conducted by clever men of business—who claim no other title than that of portrait manufacturers, and whose operators are sometimes called upon to take eighty and ninety sitters each day. I would ask what possible opportunity is there for design in photographs taken under these conditions. If a photographic artist really puts design into his picture the Registration Act will give him all the protection he needs.

I am, dear sir, yours faithfully, ALEXANDER BASSANO.
25, Old Bond Street, December 2nd., 1879.

PAINTING STUCK TO GLASS.

SIR,—I have an oil-painting on canvas (no photograph) brought me to-day. It is framed with a glass in front, and the picture is stuck to the glass in the centre. Can you advise me how to detach it without injury to the painting? A reply in your next issue will oblige.—Yours truly,
ALFRED FERKE.

253, Bute Street, Cardiff, November 25th.

[As a rule, an oil-painting should not be framed with a glass in front; and certainly not in contact. It will require very delicate manipulation to remove it with our injuring the painting, and if the portion adhering is large, or includes any important part of the picture, its detachment should only be attempted by an expert. The introduction

of a drop or two of a solvent of the varnish would probably help to detach it, but there is risk of injury to the painting.—Ed.]

A PHOTOGRAPHIC CLUB.

SIR,—It seems to me by Mr. J. S. Tully's letters in last week's number, and in that of some five weeks since, that the two London Societies must be great losers in not having a gentleman with so varied an experience as a member, as I feel sure that were he a member, the few speakers, or readers of papers, would find their proper level, and the amateur or diffident speakers would take courage, and many members, who at the present time are deterred by the clique (?) so graphically described by Mr. Tully in his former letter, would come to the front and give us their experiences; and many "modest" speakers, be they members or non-members, would enlighten us with their ideas and suggestions.

It seems a great pity that it has not occurred to some one or two members of the Societies to propose Mr. Tully as a member, either subscribing or honorary; but I am rather surprised, seeing the great interest Mr. Tully takes in the Societies, that it has not occurred to him the benefit he might confer upon inexperienced photographers by paying a visit to one of the monthly meetings of, say, the Junior Society. But, joking apart, is not Mr. Tully rather behind time in his remarks and suggestions as to the formation, constitution, &c., of the Photographic Club, as the Preliminary Committee invited, in your issues of the 24th and 31st of October, the opinions and suggestions of all interested in the formation of this Club, and also especially invited their attendance at the meeting held at the Freemason's Tavern, on the 7th of November. To neither of these three and previous invites did Mr. Tully respond, and, therefore, they were compelled to arrive "at a conclusion (not hastily) as to its form of membership and entrance fee, subscriptions, &c." Had he also have read the report of the Preliminary Committee in your impression of the 21st ult., he would there have seen that the feeling was that it should, and the committee recommended it to, be made general, and open to all interested in photography. The recommendation was accepted by those forming the Club, and the Club is, therefore, open to all, irrespective of any Society, upon going through the usual routine of proposing, balloting, &c.

There is an old saying that you must creep before you run, and the Society in its present form, though members are being rapidly enrolled, is in but an infant state; the original idea, as stated in the report, having a far wider scope than can at present be carried out. Of its ultimate success and benefits, no one who has attended its weekly meetings can have a shadow of doubt; and many of the suggestions thrown out by Mr. Tully have already been fully discussed by the Executive of the Club. Even the question of an open night and paid lecturer was mentioned at the last meeting, and will come under discussion tomorrow night.—I am, dear sir, yours truly,

C. G. CUTCHEY, Hon. Sec.

62, Gracechurch Street, Dec. 2nd.

PHOTOGRAPHIC EXHIBITION.

SIR,—Permit me a few lines in reply to Mr. Spiller. I will be as brief as possible.

The responsibility of exhibiting the pictures in question rests entirely with the Hanging Committee. Six or seven pictures were sent (I forget the exact number), a portion of which only were hung, the others remaining in the box; the Committee choosing to hang the cattle subjects in preference. Moreover, they were sent "not for competition," the labels announcing the fact still remaining on the frames.

I will now return to the broad question at issue. Mr. Spiller, in common with the Council of the Society, appears unable to grasp the difference between the amateur photographer and the professional; the former incurs frequently

a great expense in framing and getting up his pictures for exhibition simply for the love of the thing, and in nine cases out of ten, (certainly in my own case), to do what he can to enable the Society to make as good a show as possible. It is therefore a very unwise and illiberal policy to lay a tax upon him further. The professional photographer not unfrequently uses the exhibition as a means of cheaply advertising, and here I think a charge might quite fairly be made to non-members, and he must be a niggard indeed who could take exception to it. Why I, together with very many other country amateurs, am not a member of the Society would occupy too much of your space to enter into, although I am sanguine that good would arise out of it, if the matter were fully ventilated in your columns.*

With respect to the charge for rental, I had no doubt that it was applied for in very many cases, but from the fact—as I understand upon good authority—of one or two photographers not having been applied to, it does look a little like partiality; and Mr. Spiller should hesitate before he says it is not true. But perhaps the application has fallen into wrong hands, as would appear to be the case with two letters of my own, one containing a remittance for some copies of the Society's catalogue to be sent to me, and another asking if it had been received, as the catalogues had not come to hand, to neither of which I ever received any reply. I had eventually to ask a friend, as some personal inconvenience, to call and purchase copies for me.—I am, sir, yours obediently,

JOHN VAUGHAN.

Oxford, December 2nd.

Proceedings of Societies.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

A MEETING of the above Society was held in the Religious Institution Rooms, Buchanan Street, on Thursday, November 20th, Mr. JOHN URIE in the chair.

The minutes of last meeting were read and approved of.

The Secretary read a letter from Dr. Marwick, begging to be excused the honour of being enrolled Honorary President, owing to his residing in the country. A discussion on gelatino-bromide plates followed, resulting in Mr. Gilfillan promising to give a demonstration of his method of manipulation, and other members promised to bring plates for development, on condition that the Secretary would develop them before the members present.

The following gentlemen were then duly elected members:—Messrs. B. Wohlgenuth, T. Somers, D. Dow, G. C. Geric, J. Hampton, W. C. Ramsay, and R. A. Cruickshank.

Mr. BELL then exhibited a series of Irish and Scotch transparencies, by aid of the Society's lantern, accompanied by a brief description of each.

At the close, Mr. Bell was awarded a hearty vote of thanks for his services, as were also Messrs. George Mason and Co., for their kindness in lending the slides.

A vote of thanks to the Chairman brought the meeting to a close.

JAMES M'GRIE, Secretary.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE annual meeting of this Association was held on Thursday, the 27th ult., at the Free Library, William Brown Street, Mr. J. H. T. ELLERBECK, Vice-President, in the chair.

The minutes of the previous meeting were read and passed. Mr. Walter Wride and Mr. Joseph Stananought were elected members of the Association.

The Secretary then read the following

Annual Report.

"THE sixteenth annual report of the Society may be considered very satisfactory, as showing that there is no falling off in the number of members, there being now sixty-nine as against sixty-three last year.

"The meetings have been well attended, particularly when there has been any practical demonstration or exhibition of transparencies with the lantern, proving that the purchase of the lantern has been appreciated by the members, and necessitat-

* We shall have pleasure in permitting the discussion if our correspondent will initiate it.—Ed.

ing the consideration as to whether the Council would be justified in purchasing other apparatus which might prove useful in experimenting and demonstrating the various branches of photography.

"Owing to the unfavourable weather during the two summer months no outdoor meetings were held, but a very delightful excursion was made to Bromborough on the afternoon of Saturday, the 10th May.

"The following papers have been read:—'Portraiture by Artificial Light for Amateurs,' by the Rev. H. J. Palmer; 'Some Experiments with the Gelatine Process,' by H. Houlgrave; 'Notes of Comparative Experiments with Gelatine Emulsions,' by the Rev. H. J. Palmer.

"Novelties were exhibited by Mr. J. H. T. Ellerbeck, Dr. Kenyon, and others, and a comparative exhibition of three-wick *versus* two-wick lanterns was shown by Mr. Meacock.

"The gelatine processes being now the favourites of the members, numerous appliances have been shown in connection with that branch of photography, the ingenuity of the members being tried in producing means to secure rapid exposures, Messrs. Potter, Kirkby, Wood, Boothroyd, and Forrest each exhibiting varieties of rapid shutters.

"The presentation prints for 1878, and one for 1879, have been distributed to the members, and the thanks of the Society are due to Mr. W. E. Potter for the use of his negative of 'Kirkstall Abbey,' and to Mr. J. H. T. Ellerbeck for the one of the 'Castle of Chillon.' Both negatives were enlarged and printed in autotype by the Autotype Company.

"An associated *soiree* of the different societies of Liverpool connected with literature and art was held in St. George's Hall, on the 19th of February last. This Society contributed to the interest of the visitors by exhibiting a variety of photographic appliances. The *soiree* proved a great success, and it is intended to have another on the 10th December, which, it is expected, will prove equally entertaining.

"The thanks of our Society are due for the presentation to them of the *Bulletin Belge, Journal of the Photographic Society of Great Britain*, and the *Autotype Notes*."

The Treasurer's report was then read, showing a good balance in favour of the Association. Both reports were adopted.

Mr. A. Tyrer, being unable to continue his office of Treasurer, received a hearty vote of thanks for his past services.

The undermentioned officers were then elected for 1880:—

President—J. H. T. Ellerbeck.

Vice-Presidents—W. Horsman Kirkby and W. Murray.

Treasurer—E. Twigge.

Hon. Secretary—William Murray.

Council—Rev. T. B. Banner, B. Boothroyd, T. Clarke, J. A. Forrest, W. King, Rev. H. J. Palmer, W. E. Potter, Ed. Roberts, J. W. H. Watling, E. Whalley, H. A. Wharmby, and L. W. Weber.

Auditors—H. A. Wharmby and L. W. Weber.

A vote of thanks was passed to the Library and Museum Committee of the Corporation of Liverpool for the use of the room in the Free Library.

Mr. W. H. KIRKBY exhibited a portable dark tent for use in changing or developing plates. The tent was made somewhat on the principle of a Howard tent, but was capable of being used for large plates. When mounted it was square instead of conical, and folded up into two waterproof trays, forming the base, which shut together similar to a book draught-board.

Mr. TWIGGE exhibited a very compact case containing everything necessary for developing plates when travelling.

Mr. KIRKBY showed a number of plates illustrating his method of testing the sensitiveness of different gelatine plates, and Mr. Wood exhibited a print of the interior of the Picton Reading Room taken while illuminated by the electric light, the exposure being ten minutes with a Ross's No. 4 symmetrical on a Swan plate.

The Rev. H. J. PALMER then gave a lantern exhibition illustrating his summer tour in Switzerland; after which the meeting was adjourned to the 29th January next.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next meeting of this Society will take place on Tuesday next, December 9th, at the Gallery, 5, Pall Mall East (the winter exhibition of the Water Colour Society being on view), when Mr. Leon Warnerke will resume his paper on "Actinometers" commenced at the last meeting.

PHOTOGRAPHIC SOCIETY OF IRELAND.—The next meeting of this society will take place at 8 p.m. on Friday, December 12th, in the Royal College of Science.

To Correspondents.

THE YEAR-BOOK OF PHOTOGRAPHY, 1880. In order to facilitate our labours in preparing the YEAR-BOOK OF PHOTOGRAPHY for next year, we shall be greatly obliged to those of our readers who can favour us with brief practical papers on subjects arising in their experience, so that our annual may be, as it is designed, a complete record of the progress of the year, and a trustworthy practical guide for the future.

THE VAPOURS OF ETHER AND ALCOHOL.—We have received a letter from Mr. R. J. Friswell, referring to the recent remarks under the head of "In and Out of the Studio" upon Dr. Zanetti's observations on the *Hygiene of Photography*. As he points out, our contributor, usually very accurate and trustworthy, has in these remarks slightly tripped in referring to the vapour of ether as lighter than the atmospheric air. "Can your learned contributor," Mr. Friswell says, "in an unguarded moment have written the specific gravity of liquid ether for that of ether vapour. Liquid ether compared with water has a gravity of 0.723. Now the formula of ethyl alcohol is C_2H_5O , and its density in the state of

vapour, referred to hydrogen as unity, is $\frac{46}{2} = 23$. Hence, being 23 times as heavy as an equal volume of hydrogen at the same temperature and pressure, it follows by a simple calculation that it is 1.6 times as heavy as an equal volume of air at the same temperature and pressure. The formula of ethylic ether is C_2H_5O .

This gives $\frac{71}{2} = 37$ times the weight of an equal volume of hydrogen under like conditions, or 2.5 times the weight of an equal volume of air. After all, therefore, Dr. Zanetti is right, and your contributor would have been more happy had he taken the trouble to find out that the 'knave' was not so 'absoluto' without good cause." As we have already said, there is an undoubted slip, possibly arising, as Mr. Friswell suggests, from confounding for the moment the vapours of ether with liquid ether. The vapour of ether has a density of 2.58, a circumstance which lends itself to the ventilation of dark-rooms. We have in more than one article on this subject recommended a grating in the floor of the operating-room, through which the vapours of ether and alcohol falling, as they do, might pass away. We have also given a caution, which we may renew here, that when a bottle of collodion or ether is broken or knocked over in the dark-room it is dangerous to place a naked light on the ground to look for the extent of the mischief, as the light on the ground, or held low, would be most likely to come into contact with the heavy vapour. We are obliged to Mr. Friswell for correcting the *lapsus*; he, like Hamlet's "absolute knave," will have us "speak by the card."

B. L. B.—So far as experience goes, gelatine plates possess very excellent keeping qualities, both before and after exposure; how long we cannot with certainty say: several months.

GELATINE.—We should recommend you to add your bad emulsion to your waste just as it is, and send to the refiner.

IGNORAMUS.—Captain Abney's address is 3, St. Augustine's Road, Kensington.

HIBERNICUS.—The address of the London agent of Messrs. Trapp and Munch, is Budge Row, Cannon Street, E.C.

NEMO.—The intensifier to which you refer was the iodide of mercury. It is made by mixing a solution of iodide of potassium with a solution of bichloride of mercury; the strength is not important. Take, say, a 10-grain solution of the mercury salt, and add to it a 10-grain solution of iodide of potassium, continuing adding until a precipitate is thrown down, which will be red iodide of mercury. Then continue adding the iodide solution until the precipitate is redissolved, and you have your intensifying solution. But bear in mind that negatives intensified with mercury are apt to grow more intense under the action of light in printing.

G. R. D.—Your ordinary gold toning solution would not answer well for toning transparencies. The solution should be stronger. We prefer about two grains of chloride of gold to the ounce of water, neutralized by chalk. The transparency should be thoroughly fixed and well washed before applying the gold solution. It is better to let the toning proceed until the transparency shows alike at the front and back, and is a fine pure black tone. A black tone is best for lantern purposes, but the image should be thin rather than dense.

B. F. R.—The reticulated network on the negative is the fault of the collodion, which has probably been made with weak solvents, that is, there is too much water present. Sometimes it is the fault of the pyroxyline. But in any case there is no remedy but discarding the collodion. It might be mixed with a new good sample, but care should be taken not to spoil the whole. There is no remedy now for the reticulated negative.

The Photographic News, December 12, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

COLOURED CHEQUES AND PHOTOGRAPHIC FORGERIES—THE SUN'S RAYS AS A MEANS OF RESEARCH—LOOKING BACK AND LOOKING FORWARD.

Coloured Cheques and Photographic Forgeries.—The London and County Bank has just followed the example of several other London banks, and caused to be printed over its cheques in part the name of the establishment in very small letters, the words being repeated over and over again so as to form a sort of pattern. This microscopic printing is in colour, and the reason of it is evidently twofold. You cannot erase a word or figure upon a surface made up of small print of this kind without erasing some of the tiny words as well, and as these obviously cannot be restored, there is no way of covering up such erasure; in the second place the printing in colour of such tiny letters is deemed sufficient to baffle any attempt to copy a cheque by means of photography. No doubt the bank authorities are right in their conjecture that it would be impossible to secure a copy of one of their cheques before the camera, printed as the document now is; but for all that we deliberately give it as our opinion that a cheque of this kind is not nearly so safe as the finely-executed cheques in plain black and white of the Bank of England. Any photographer who has taken an interest in recent trials of forgers in Paris, and has seen how successfully photography has been used in the imitation of coloured cheques, will be disposed to agree with us. Even the blue notes of the Bank of France have not escaped these *chevaliers de l'industrie*; and it is but a year or two ago that the French police were enabled to make a seizure. Just after the Franco-German War, when bank notes were exceedingly prolific with our French neighbours, there were large numbers of the spurious blue notes in circulation; and on the principle of setting a thief to catch a thief, the Direction of the Bank of France at once invoked the aid of photography to detect photographic forgeries. M. Gobert, a well-known member of the French Photographic Society, and an accomplished photographic chemist, was retained by the Bank of France as adviser, and it is, in a great measure, due to him that abatement of photographic forgeries in France is due. Many years ago, we remember, Mr. Spiller was called in as scientific referee in the matter of colour printing upon cheques, and gave much excellent advice upon the subject; but, unfortunately, our banks do not keep pace with the times, and what was impossible twenty years ago, is perfectly feasible at the present moment. The German authorities used to consider that they had altogether defied imitation by having recourse to very fine printing at the back of their bank-notes—similar to that on the cheques of the Cheque Bank, London and Westminster, London and County, &c.—this fine printing, which was in black, setting forth the severe penalties which would be visited upon those who endeavoured to forge such documents. This fine print, rather than acting as a barrier, resolved itself rather into a premium for copying by photography. The bank-note was put under a microscope or magnifier, and the tiny printing thus enlarged, it could then be imitated by an engraver, and the photographer had simply to photograph the copy in order to produce the small printing. And so we take it that the microscopic printing in colour, rather than acting as a safeguard against the production of spurious cheques, will render the matter somewhat more easy. The colour—whether it is applied as a simple tint, or in the form of microscopic words—serves the purpose in a forgery of covering up defects in the engraving of the cheque. Rather, therefore, than adding to the difficulty of copying, it rather lightens it, since the work not being in pure black and white need not be so faultlessly executed. This is why the blue applied to the Bank of

France was no protection. Photographers, now-a-days, know a good deal about the sensitiveness of various collodion films for different colours, and are also well versed in what may be done by under-exposure and over-intensifying, and *vice versa*, and there are few tints or designs that they cannot copy one way or another; and by having recourse to combination printing, a skilled operator will overcome the most stubborn opportunities. But there would be no need, of course, in order to imitate a modern cheque to copy the minute blue or pink printing upon them. This would be produced of large size, a reduced negative executed with the type of proper dimensions, and impressed upon a collodion film, would be capable of yielding any number of impressions and in any colour; while as to fineness of the type and freedom from blurring, the result would simply be more perfect than the majority of cheques with which the public deal. Anyone who has seen the fine details of a map reproduced upon a collodion film, the delicate shading, and minute lines, will readily believe this, while we may point out that scarcely less perfect work is produced now-a-days by a phototype process. The finely executed drawings we see upon the *Graphic Programme*, and other theatrical publications, which are as delicate as anything done by engraving, are all prepared by the aid of photography, the original sketches, in the first instance, being produced many inches high. The lines are fine and black in the originals, and in the course of reduction become, of course, exceedingly delicate; thus it is that the drawings appear so refined beside an ordinary wood-cut. We have recited these facts to show how the graphic arts have improved of late by the aid of photography, and to point out that what might have been impossible some years ago is perfectly possible at the present day; and to this fact the Bank authorities should give attention. Certainly, microscopic printing in colours cannot be relied upon at the present moment as a safeguard against the forging of cheques; for we fully believe that a skilled hand would have more difficulty in counterfeiting the black and white document issued by the Bank of England than one in which a combination of colours is to be found.

The Sun's Rays as a Means of Research.—We see that M. Raoul Pictet, whose name is already well known in connection with the liquefaction of gases, is about to make use of the sun's rays in a research on the metalloids. He hopes to be able to disassociate the metalloids by bringing them into the focus of a huge metallic mirror, and thus concentrating upon them heat rays of a very high temperature. The experiment is to be carried out on a very large scale, and doubtless, if the experiment which is to take place in the clear atmosphere of Geneva, is conducted at a period when the full benefit of the sun is to be obtained, the result will be well worth watching. The experiment will be for many reasons unique, for a research of this nature has never been made on the large scale contemplated by M. Raoul Pictet. Now that Mr. Norman Lockyer and M. Victor Meyer have led us to believe so much in the matter of disassociation of the so-called elements, the research of M. Pictet will be followed with considerable interest by the scientific world, and we only hope that it may be instrumental in confirming one way or another the truth or fallacy of some of the theories that have startled us of late.

Looking Back and Looking Forward.—To the versatile author of "Looking Back" the readers of this journal are indebted not only for an entertaining series of papers, but for the communication of much dearly-bought experience. Many a photographer has rashly done what the author of "Looking Back" so graphically describes, namely, rushed into an undertaking without counting the cost; but there are few who can so vividly bring home their experiences to others. Whether it was photographing a Polar bear on its native ice in Iceland, or taking a servant girl's portrait somewhere in the Lower Road, Islington, our author's descriptions carried with them the stamp of reality, and there are few among us who do not imagine that we have taken that same

voyage out and home to the dreary Arctic Ocean, in company with a lot of noble swells, who did not seem to appreciate their voyage quite so much as they thought they would. Our author lets us see the thorns quite as much as the roses that beset his path; in fact, he lets us feel them at times, and hence it is that we entered so thoroughly into his joys and sorrows. Let us hope that the pen which has given such enjoyable entertainment, will not be allowed a long rest, but that it may soon be at work again detailing yet more interesting experiences. Our readers, we are sure, will be "Looking Forward" to such an end with pleasure.

FRENCH CORRESPONDENCE.

PHOTOGRAPHIC STUDIOS IN PARIS DURING THE SNOW STORM—TWELVE THOUSAND CELEBRITIES ENTOMBED—MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE.

The Snow Storm in Paris.—Within the memory of man there has never been such a fall of snow in Paris. Since Thursday last the storm has not ceased, and as yet it shows no signs of ending. The business and current life of the metropolis are in fact quite suspended. Everywhere means of communication are interrupted; the tramcars have stopped running; it is impossible to take either cab or omnibus; the posts are all behindhand, and the household supply is cut off; as regards fire and light we are already straitened, and are threatened with entire failure of both. Such, in a word, are the evils wrought by a persistent fall of snow, which defies all the efforts of the local authorities to remove it. Photographers have more especially had to suffer in this unparalleled visitation; they have had to endure, so to say, a second though quite unexpected invasion, which has vividly recalled to mind the horrors of the late siege of Paris. People are anxiously and generally asking when will this climatic severity cease. Of course, under such circumstances, customers are out of the question; no one who is not compelled will venture into the streets. Besides, all the photographic glasshouses are covered with such a deep layer of snow, that daylight can scarcely penetrate to them. There is not even light for the purpose of copying, which is generally the occupation of the assistants when no sitters make their appearance. Traversing the covered passages and arcades so numerous in Paris may give some idea of the state of things in the studios; they are like so many subterranean cities where, notwithstanding the display in the shop-window, life seems to have quite died out. The only sign of vitality is the faint flicker of gas, astonished at having to struggle with some daylight which enters at the sides. Above, it is all night; below, we have the pale light reflected from the snow, like moonlight in the wrong place. What a pity it is we cannot avail ourselves of photography itself to reproduce this effect! But then the practice of photography, the same as that of every other profession, is actually suspended in Paris. The only occupation open is to repair the damages caused by the snow, and to take measures for preventing those damages from being made worse; and this is no easy matter, since the police regulations forbid the snow which has accumulated on the roofs from being thrown into the street.

Entombment of Twelve Thousand Celebrities.—Moreover, several photographic studios have actually given way beneath the weight of the white shroud that has fallen from a quarter whence the photographer expects generally to get nothing but light. Among these constructions, that of M. Pierre Petit has had the most to suffer. This vast establishment includes several out-houses from 10 to 15 centimetres in length by 5 in breadth, where are kept the negatives of the portraits of a large number of celebrated persons still living. This collection, which has been growing since 1855, is well known to the editors of the illustrated journals, who often have recourse to it. About eight o'clock in the morning of Friday last, the glass roof, formed of thick squares fixed in iron frames, began to give under the weight of a solid mass of snow more than a metre in depth. M.

Pierre Petit, fearing the complete collapse of his glass-houses naturally proceeded to take efficacious measures against the destruction of his property, but found himself met at the outset by the regulation alluded to above, which prohibits the removal of the snow; though it is fair to suppose that so extraordinary a predicament had never been contemplated. The travels of the unfortunate photographer on his miserable errand seemed to him to be never ending: seeking only a simple permit for the removal of the snow, he was sent about from Peter to Paul. The Commissioner of Police declared himself to have no power, and referred him to the *Mairie*; from thence he was sent to the District Surveyor, and he was from home. Then he went to the Chief Engineer of the Board of Works, who politely informed him that he was not permitted to trench on the duties of the Way-warden; unfortunately, the latter functionary was engaged on works at a distance, and none of his under-strappers dared to take on himself to give an order in the absence of his chief. Meanwhile the danger was rapidly increasing, and all the time that poor M. Petit was running about for official help he was trembling with fear that his magnificent studios were being completely destroyed. At last, luckily for himself, he decided to infringe the law; so he returned home and set all his employés and workmen at work to remove the accumulations of snow. M. Pierre Petit is not yet aware of the amount of the fine he has incurred for having ventured to save his own property, but he finds consolation in the fact that he has been able to avoid the disaster which threatened him; his only loss will arise from the partial falling in of the out-houses. Even then, many of the negatives which were kept in boxes he has succeeded with some difficulty in dragging out from beneath the snow. In this way the existence of twelve thousand celebrities in effigy has been saved. Perhaps the number of probable victims has been exaggerated, but we will leave the responsibility for the announcement of the figures to the Editor of the *Petit Journal*, who has excited the imagination of the readers of his widely-circulated paper by an article bearing the sensational title of "Twelve thousand celebrities in the snow."

Meeting of the Photographic Society of France.—Notwithstanding the frightful weather, the Photographic Society of France had the courage to hold its ordinary monthly meeting. The agenda paper presented no subject of any great interest. M. Arsène Péligny exhibited some negatives taken on paper prepared with a mixture of castor oil and alcohol, instead of being waxed, as in the ordinary way, and M. Aimé Girard showed specimens of a pyroxylite which had been highly spoken of. Besides these presentations, only two communications worthy of notice were read, both on subjects which are familiar to the readers of the PHOTOGRAPHIC NEWS. The first was a description of M. Germeuil Bonnaud's process for photographic printing in colours, the second an account of the Luxograph. Some photographs taken by means of this latter apparatus, which is as yet but little known in France, were exhibited by the agent for the sale of the instrument in Paris; he was unable, on account of the bad weather, to bring the apparatus itself to the meeting. Let us hope, on behalf of the Luxograph (which would not be out of place in the present condition of the weather), as well as on behalf of the other subjects that are to be brought forward, that the next meeting of the Photographic Society of France may be favoured with a milder temperature. K. VERSMAETEN.

A FEW HINTS ABOUT COMPOSITION LINES IN PHOTOGRAPHY.

BY EDWIN COCKING.*

MR. VAL PRINSEP, A.R.A., in an address delivered lately to the students in the City School of Art, said, that "many students spent year after year in acquiring the language of

* Read before the South London Photographic Society.

art, only to find in the end that they had nothing to say." Now I suppose that in photographic art the converse may be said to prevail, viz., that very many can say much without having studied the language at all; in other words, that the facility whereby a photograph of anything visible can be produced, has for a time almost shut out the necessity for acquiring any knowledge of the principles which obtain in fine art, but which can also assist the student in photographic art; and it must give unbounded satisfaction to those more cultured to find that at the present time the absolute necessity is felt for a true and conscientious knowledge of art principles, so far as it is possible to utilize them in the practice of photography.

The South London Society having adopted a very promising mode for encouraging such studies, a few hints which may help forward this desirable object may not be out of place.

And here let me digress (although it is closely associated with our subject) to notice some remarks recently published that there is "no design in photography." This is to me so utterly untenable, that I cannot understand how any person with even moderate powers of observation can venture to hold such an opinion. I contend that even the very commonest photograph of a figure or landscape you can find, bears upon its face the design of its author, because if in any the slightest degree he moves the object, figures, or moves his position in landscapes, it must be admitted that in so doing he had a design, and thus proclaims most unmistakably that he *did* what he was able to do from his standpoint, which probably may be at the "zero" of ability; and so some one a little more cultured sees what is bad, and then tries in his work to do better. Does not this individual thereby show that he also has designed something? Carry this principle out through a higher development of mental power, and you arrive at something still better in result, which, call it what you like, must still be *design*, viz., *something conceived and attempted to be carried out*.

It is our desire, then, to assist in promoting a closer attention to those rules which, instinctively, as it were, the masters in all art productions have adopted.

I have frequently shown that there is so little that is common in the mode of study to both the fine art student and the photographic art student, that it becomes difficult to lay down, or even suggest, lines of study, derived from fine art, which shall be easily understood and applied to photographic art. I shall therefore at this moment only attempt by a few remarks and suggestions to indicate a line of study which I think will be found to be useful.

In all pictures, whatever may be the position of the figures, certain lines will arise in the placing of such figures together which become more conspicuous than others, and these require to be composed in such a manner as to satisfy some instinctive artistic law, which requires harmony in the parts, besides illustrating the sentiment or subject of the picture. If the study be a single figure only, there is plenty of opportunity for exercising thought. As a simple illustration: suppose the line of some flowing drapery leans toward the right hand corner of the picture, some object giving a strong outline must be introduced in a similar way on the opposite side, viz, leaning towards the left hand corner. This will balance the first leaning line, by being constructed upon the pyramidal form of composition; the smaller lines can be again balanced by similar small lines on the other side, and these will then require some perpendicular lines to satisfy the instinctive law I have alluded to. Then there are the suggestive lines formed by small objects which can be introduced into a picture made up of *realities* such as a photographic study must of necessity be. This simple form of composition based upon the sloping sides of a pyramid is always the safest, and will be found to be the most instructive in practice. These and other lines of composition which will arise out of my subject thus become matters of harmonious arrangement. But we want to express some particular action or sentiment: well, then, the composing lines ought to suggest such ideas in another who sees the result without knowing it—

that is, instinctively; as, for instance, beauty, softness, repose, &c., can only be suggested or expressed by continuous lines running on with very little bending in them—in fact, no sudden turns or twists. If ugliness, violence, passion, &c., be desired, then arrange the lines angular, sudden, and opposed to each other. These are extremes: the study will consist in finding out just the *mean* between these opposites, which also expresses any sentiment between beauty and ugliness, at the same time the eye must be satisfied with a regular balance of parts.

You must all call to mind Rejlander's picture of "Homeless," which by its angularity of composition suggests the idea or sentiment he wished it to do; whilst at the same time the eye is satisfied with the equal balance throughout; and thus, to use another simile, the piece was set in a minor key, yet the laws of harmony were strictly and learnedly used.

It will be thus seen that in composition the prominent lines of the picture have not only to express something special, but have to be considered in harmonious relation to each other. So that the lines of the figure, the lines of the draperies, the accessories, the carpet, and even the decorations on the walls, must all be utilized for the purpose, and made subservient to the dominant idea.

Some time ago, in a paper I read upon art in relation to photography, I stated that there were published numerous designs (in outline only) by German and English artists, and I recommended that the photographic student should study these, and endeavour to find out the meaning of the lines composing the pictures. Also I would very strongly suggest that use should be made of those excellent German and French small wooded jointed figures for experimenting with for single and combined positions. Having settled the position, it is then easier to place the living model in the same pose, and thus much time is saved; and as the photographic art student does not require to train his *hand* in any way for the production of a high order of photograph, the time given to the *head* study can be utilized at once, and practically put before his taste and judgment. In this respect he has an advantage over the artist, who must patiently work out his ideas. At the same time, the photographer must never think that his work is therefore easier, and much good will arise if those who take part in the South London Society's competition will take all possible pains to produce works evidencing that thought and care have been bestowed upon their productions.

AN APPARATUS FOR THE CLARIFICATION OF GELATINOUS SOLUTIONS.

BY T. BOLAS.*

THE improved vessel for containing ferrous oxalate developer which Mr. Warnerke exhibited at the last technical meeting of this Society reminded me of an arrangement which I have found to be exceedingly useful in dealing with gelatinous solutions and other viscous fluids which tend to retain air-bubbles in suspension.

A bottle having two necks, one at the top and the other about an inch from the bottom, is procured, and to the lower neck there is fitted, by means of an India-rubber cork, a glass tube bent something like the neck of a coffee pot. If a gelatinous solution (not quite free from intermingled air-bells) be now put into the bottle, the necessary temperature being maintained by means of a warm water bath, the air-bells will gradually rise to the surface; after which the clear liquid may be decanted through the spout-like glass tube. In order to expedite the rising of the air-bubbles to the surface, the upper neck can be connected with an air-pump, so that the space over the gelatinous solution may be rendered vacuum, but in this case it is of course necessary to close the end of the spout by means of a cap or plug of caoutchouc; and it is convenient to adapt a thermometer into the neck in such a manner that the bulb of this instrument shall be immersed in the gelatinous liquid. Both these latter ends may

* Read before the South London Photographic Society.

be attained by fitting into the upper neck a glass tube a couple of inches long by half-an-inch in diameter, and provided with a side branch for connection with the air-pump ;

while the thermometer passes through the upright tube, where it is fixed by means of an India-rubber cork. A caoutchouc tube with coiled wire inside is convenient for connecting the apparatus with the air-pump, as such a tube does not collapse, in consequence of the pressure of the external air.

Here, then, is the complete apparatus ready for use, and I feel sure that anyone frequently using or experimenting with gelatinous solutions will find it exceedingly convenient in actual practice.

A FEW REASONS WHY PHOTOGRAPHERS SHOULD STUDY PRACTICAL CHEMISTRY.

BY THOMAS W. DRINKWATER, M.D., F.C.S., &c.*

In these days of thorough education no excuse is needed for such a paper as this beyond one for my inability I fear to make it interesting.

Technical education in all its branches is claiming the attention of those whose business and duty it is to teach, and before long we may hope that the reformatory wave that is now sweeping through the land may do some good, and that our college and university authorities may see their way to establishing chairs of technology in their respective schools.

Hitherto the systematic study of photography has been almost entirely neglected; in fact, I only know of one college where it is taught as a separate branch.

You will all, no doubt, agree with me when I state that photography is a most important adjunct to many branches of technological and mechanical industry, and to it we owe much of our knowledge of many sciences. If, then, you admit it to be a useful adjunct to science, is it not fair to urge for its study in a scientific manner?

You must remember that photography possesses its science as well as its art. The science can be taught, but the art cannot. It must come intuitively; and the object of my paper to-night is to ask those of you who already have this art intuitively planted in your souls to seek for the science, so that you may be better able to use those gifts which belong to you naturally.

How many photographers go through their daily work—exposing, developing, and printing—without either knowing or caring to inquire into the cause of the various effects they are producing. They know that iron when applied to an exposed sensitive plate develops in a mysterious manner the hidden image; but the reason of its so doing is as obscure to their minds as the latent picture was to their sight. Now this is not as it should be.

All genuine photographers that I have ever had the pleasure of knowing have always been ready and willing to seize and improve any mechanical portion of the work which may suggest itself to their mind; but how few are there who devote any attention to the chemical portion?

Looking at the photographer's work from one point of

* Read before the Edinburgh Photographic Society.

view, I cannot help comparing him to a chemist carrying on a series of experiments in his laboratory of the most delicate nature, in which the smallest divergence from the right path, or the slightest error in manipulation, or the least variation in the composition of his chemicals, will cause an utter failure.

We should all ridicule the idea of any but a skilled chemist carrying on such an investigation as this, and yet we know of hundreds of photographers doing precisely the same thing every day of their lives, without, in many cases, even knowing the names of the elements which enter into the composition of the compounds they are using. Do not think I am swinging the lash too freely. I am instancing extreme cases only to add greater force to my argument.

Of all the collateral sciences, then, which lend their aid to photography I place chemistry first—not because it is my profession and hobby, so to speak, but because the truly practical portion of photographic science is more ultimately dependent on chemistry than it is in light and optics.

So much in the way of general reasons. Let me now particularise a little more.

In the first place, I should recommend the study of practical chemistry as a matter of general education, for a profession which deals in science and art should be well educated. Without education what use can be made of inventive art? I fear very little. The seed may be there, the embryo may only need development, but if the soil, so to speak, lacks education true art can never flourish. In certain applications this education need not be scientific, but in photography there must be a certain amount of scientific knowledge acquired before the education can be called complete.

Next, as an aid to manipulation, I know of no work more calculated to teach a man the use of his hands than the practical study of chemistry, and the more limited the means the more benefit to be derived. It is not the man who is surrounded with a chaos of mysterious apparatus, in which polished brass and crystal shine conspicuously, that does the useful work. It is the student who, by want of more expensive luxuries, contrives and almost creates useful apparatus out of the ordinary surroundings of everyday life. Do not be discouraged, therefore, at the outset of your studies by the costliness of your apparatus. A few shillings will supply all your wants. With half-a-dozen test-tubes, a spirit or gas lamp, and a few reagents an operator can, if possessed of the necessary skill, carry on the most complicated analysis successfully. Working in this way, then, will give you manipulative skill, and I need not dwell on its value to the photographer. It must be too well known to you all.

As my next reason on the score of economy, and under this heading, one might find numerous applications. In the present day no fraud is so rife as adulteration. Food, drugs, and chemicals—nothing is spared by the hand of the adulterator. Many of the photographic chemicals are expensive, and offer every temptation for fraudulent substitution. So skilfully is this done in many instances that a mere inspection, even by the most practised eye, can hardly detect it, and it in consequence lies latent working all manner of mischief until brought to light by means of the chemist's test-tubes and reagents.

Adulteration may be either intentional or accidental. In food and drugs it would generally come under the former heading; in chemicals it would be more likely to come under the latter. The very process used in the manufacture of certain compounds may introduce an adulterant which the imperfection of subsequent treatment may fail to remove. As an example, take the preparation of copperas, or "sulphate of iron," to call it by a more correct and scientific name. To make this in a pure condition we would take pure iron, dissolve it in pure sulphuric acid, and evaporate the solution so obtained to crystallisation; but if the manufacturer adopted this process it would not pay. He takes iron pyrites as found native, consisting of sulphide of iron and copper, and roasts the mineral in a current of air, thus converting the

sulphides into sulphates by oxidation. The friable mass is thrown into water, and the solution crystallised in the ordinary way. What is the consequence? The sulphate of iron so produced contains a small amount of sulphate of copper. Not that this would act in any deleterious manner. This could not be called fraudulent adulteration. Now, if a photographer were versed in practical chemistry he could not only detect the adulteration but remove it by suitable means.

Perhaps nothing tends more to failure in photographic processes than impure chemicals, and yet in our ordinary photographic literature it is the subject least alluded to. You may say you buy your chemicals from a well-known and respectable firm, who could not for reputation's sake sell inferior articles. All very true; but it is a good rule never to take anything for granted if one has the means to find it out for himself.

Another example:—Every now and then we hear a good deal about the fading of silver prints, and the effect is said to be owing to the imperfect washing of the paper after fixing with the hyposulphite solution. This may be the case in many instances, but it may be due to other causes; and one source of such an evil has been very much overlooked both by writers on and practisers of photography, viz., the quality of the card or millboard on which the print is mounted. As many of you are, no doubt, aware, white paper and cardboard are during their manufacture submitted to the bleaching action of chlorine. After performing its office the chlorine must be removed, so as to prevent after-deterioration of the paper. To do this by means of plain water would be both a tedious and expensive operation, so the manufacturer brings to his aid some chemical which will at once convert the free chlorine into a soluble acid easily and quickly eliminated by washing. The compound most commonly used is hyposulphite of soda, under the technical name of "antichlor;" and as photographers we can easily understand how difficult it is to remove all traces of this compound from the pulp; consequently, if we submit to a chemical examination the generality of commercial specimens of white paper and cardboard, we shall find variable quantities of the much dreaded hyposulphite entering into the component parts.

Supposing, now, a print to be mounted on such cardboard, can we wonder at its want of permanency? The photographer should then be able to test his card mounts for himself, and thus avoid annoyance and vexation of spirit, besides, perhaps, a blot on his reputation as a skilful artist, which would be felt in the most tender part of all of us—the pocket. Without a fair knowledge of chemistry can this be done? I think not. We may learn to test for the presence of a few impurities in a mechanical and empirical manner; but let some occasion arise to use this knowledge in a way out of the ordinary beaten track, and where are we? Our knowledge is useless, and our reagents and test-tubes have no occupation. It requires that peculiar tact and ever-ready resource which is only to be acquired by the study of practical chemistry to overcome such a difficulty. One may be able to recognize hyposulphite when in its solid form, or even in solution, with a mere smattering of chemical knowledge; but when it is mixed with paper or some other unusual substance none but the man who has studied analysis practically and systematically can recognise it. I might bring many such instances under your notice if time permitted, but one such will, I am sure, be sufficient to make clear my meaning.

I have often spoken and argued with a view to procure the more general teaching of elementary chemistry in schools, if for no other reason than to make the scholars systematic. If a man be truly scientific he will also be systematic. They are synonymous terms—inseparable virtues. In a profession like the photographer's, where system is everything, where method and order gain the victory over irregularity and confusion, is it not more important that we should study a science which, if we already possess these re-

quirements, will strengthen and develop them in a more marked degree, whilst if we are not so fortunate as some of our brethren, will create, so to speak, the virtues which we lack? On this score alone I would strongly urge upon you to undertake the study.

In all trades or professions there is, or, rather, should be, a general desire for advancement—an ambition to do as great as, or greater, deeds than those who have gone before and left their names indelibly fixed on the tablets of honour and fame. Such an ambition can never be gratified by one who does not master every detail of his work. If we wish to be a Daguerre, a Lambert, or a Wortley, we cannot stand still. Let us once stand still in this world and we immediately commence a retrograde movement. Photography is no exception to the general rule. We must either advance or go back; there is no middle course at our option. We must disbelieve in the proverb of there being "nothing new under the sun." We must search for the hidden, invent for the future, and improve the past. Can all this be achieved without the practical application of chemical science? I venture to say—no.

If we look back and glance over the names of those who have advanced by their skill and knowledge the science of photography we shall find they have all been chemists. The majority can hardly be called practical photographers; in fact, it comes to this—that photographic science has been more advanced by men outside the immediate photographic circle than those within it. Why are matters thus? Simply because the ordinary photographer pays no attention to practical chemistry. He works in the daily rut, and never gives up any well-earned leisure time to the pastime (for he can make it a pastime if he choose) of chemistry. Surely the practical artist, with a knowledge of the thousand-and-one necessary details that are needed to produce a perfect picture, if he only possessed a knowledge of chemistry would be in a much better position to advance his profession than a man who had the chemical knowledge combined with only a smattering of photography.

A little chemistry and a great deal of photography can do more in this direction than a little photography and a great deal of chemistry. The chemist who undertakes an investigation of this kind comes into the field in the latter condition, and, in consequence, only slow progress is made; that is to say, comparatively slow progress. Now, if the photographer could enter on his researches in the former state, we might look to rapid advancement in every department of the science.

There are many other reasons which I might bring forward, but they are only of major importance individually and not generally or collectively, and therefore I will not allude to them. There are little circumstances constantly arising either in the dark room or studio when, if you only think for one moment, the importance of even a light knowledge of chemistry will become patent to you.

I am not asking you to undertake a difficult or uninteresting study, but one which discloses fresh beauties and applications at every step of advancement. As you proceed with your study you will soon be made aware of its value, and may be enabled not only to advance your own science, but even give aid to the chemist. There are many phenomena connected with the chemical actions of light at present unexplainable, and which a scientific photographer could do more to elucidate than many a chemist.

Walking side by side in this manner, what mutual benefit might accrue? If I have succeeded in showing and convincing you of the value of my reasoning, as I trust I have, I am sure you will not require any stronger persuasion to commence work at once; and then, to use an old quotation, we may soon have chemistry and photography like—

"Two souls with but one single thought;
Two hearts that beat as one."

WATER FOR NOTHING.*

"WATER for nothing" is the boon which Mr. Shirley Hibberd offers to every householder. Whilst corporations and municipal bodies are discussing the respective advantages of tapping remote lakes, of boring deep artesian wells, and of getting supplies from rivers with as little taint as possible of sewage or chemical refuse, with which to satisfy the domestic necessities of the millions, Mr. Hibberd points out that a perennial supply of the purest water is wasted, or worse. Worse, since its entrance into the ordinary sewers materially helps to complicate the question of the profitable dealing with sewage. As Mr. Hibberd observes, "millions have been expended on public water supply, but the results are unequal to the requirements of the case, and the supply must be increased by the expenditure of more millions."

The "water rate" is generally an unpopular tax, and is often very unfair in its apportionment. Mr. Hibberd points out a simple method of avoiding it altogether. Sheer ignorance of the boundless supply awaiting acceptance, without money and without price, can alone explain its long neglect. The eager reader is enquiring "Whence is this supply to be obtained?" And Mr. Hibberd's reply is, "From the heavens above us." It is simply the rainwater which we waste. Let no one turn away with disappointment or incredulity. The author is not one whose word can be slighted. Mr. Shirley Hibberd is best known as a high authority on horticulture, and one of the best writers of the day on the subject; but he is also well known as an original thinker and natural philosopher, and can well justify any project he places before the public. He shows that the rainfall in England is ample to meet the needs of domestic life, and that it is better fitted for that purpose than the best which is found in the ordinary water supply of the country at present. Properly received and stored it is *pure water*, and requires no certificates of its degrees of hardness, or the low percentage it contains of contamination. He also shows that it can be collected and stored in a state of purity by very simple and inexpensive appliances. We fear that we are to some extent diluting his clear and vigorous statement of the case by using our own words. We will, therefore, briefly quote the pamphlet, which we commend every one to read. He says:—

"It is certain every man has at his command, to a very great extent, the means of securing an abundant and perfect supply of water by the simple process of utilizing the rainfall. In this year of agitation on the subject the rainfall has been more copious than has been known for many years, and has been almost wholly allowed to run to waste. There has been 'water, water everywhere, but not a drop to drink.' Nor is the wanton waste in the rainfall the only sin society has to answer for in the pre-

sence of a bountiful Providence. The cost of its removal by means of channels and drains is enormous, and the addition of the rainfall to sewage proper renders the utilization of sewage impossible by reason of its unmanageable bulk and excessive dilution. Thus the rain that we refuse to catch and keep adds to the burden of the ratepayer by every drop that falls, and is made the means of conveying to the sea, to be lost for evermore, those constituents of the soil that are the causes of fertility. We are prospecting among the hills and boring into the depths of the earth in search of water, while, if we would but look to heaven, we should have plenty, and the Divine assurance of heavenly drink for evermore. The rainfall in London averages twenty-five inches. One inch of rain falling on an acre of ground is 2,622 gallons, and if there are twenty-five houses on that acre of land, the total annual rainfall is exactly that amount for each of them. Suppose only one-tenth of the total fall is caught and saved for household purposes, that is 2,622 gallons per house. The rainfall of the present year will greatly exceed the average, but exceptional circumstances should not be brought into the present consideration."

Whilst admitting the amplitude of the supply, many will at once demur to the quality. Associating the idea of rain water with the dingy fluid which, after washing dirty roofs, is stored in half-rotten casks at once foul in appearance and flavour, they will be disposed at once to dismiss the idea of its use in cookery, still more as a beverage, as would Mr. Hibberd himself. But let the objector ask himself whence the total supply of water at present consumed is obtained. It is simply rain water collected from a thousand hills receiving a thousand forms of contamination from which it requires purifying before it is accepted for domestic and other use. Let Mr. Hibberd again speak. He says:—

"The proposal to use rain water for any but the roughest purposes will surprise a few, and annoy many. Rain water is in bad repute, more especially in towns. Here and there we meet with an ill-looking water butt, from which may be drawn a sooty fluid that is less remarkable for its sootiness than for its offensive odour, and sometimes for the plenitude of mysterious life it contains in the shape of wriggling and jerking creatures, whose activities indicate that the water must contain something substantial for their sustenance. It might be better to be content with the water supplied by the companies than to drink such filth as this, but the filthiness is profoundly instructive. The companies travel far and incur great expenditure to discover springs and wells; they construct great engines and filtering beds, and in various ways make a business of obtaining and preparing water for domestic use. But when the householder enters into the business for himself he sticks up a secondhand run puncheon, without a cover, in the full sun, exposed to all weathers as a contemptible thing, and in due time complains that it stinks! Well, a leg of mutton would do the same thing. If water is worth having, it is worth respectful and reasonable treatment, and when rain water obtains this treatment it is better in appearance, better in flavour, better for cooking, washing, and all other domestic uses, than any other water, no matter from what source obtained. This subtle element acquires contamination of some sort the instant it touches the earth, and the contamination is in exact proportion to the nature and solubility of the earth that constitutes the watershed, the watercourse, the bed of the lake and the reservoir. Hence, indeed, the endless diversities in the characters of waters, for wherever we travel we meet with water characteristic of the place—often too characteristic—so that it becomes a serious question how best to die with it, or live without it. The immense use of aerated waters and 'mineral' waters generally affords testimony to the unsatisfactory nature of the prevailing supplies. But it is a grave question whether these conduce to the health of those who consume them. This, however, is beyond dispute, that many forms of disease, not the least of the number being urinary calculus and goitre, are direct results of the habitual use of waters impregnated with mineral substances that are never properly eliminated from the frame. The danger of mineralization is made manifest in the constant endeavours of all concerned to obtain *pure water*, and the scrupulousness with which the percentage of organic and mineral matters in any particular water are noted and commented on. And when the purest water obtainable is obtained, it is but rain water with the least contamination possible. What else is the water of Loch Katrine? The reason of its purity is, that it is

* Water for Nothing. Every House its own Water Supply. By Shirley Hibberd, F.R.H.S. (London: Edinham Wilson.)

fed from a rock which yields but infinitesimally of its mineral constituents to the solvent powers of water."

The objectors, having admitted that the public water supply, through whatever source it may reach the consumer, is simply rain water, will not be altogether silenced. Some of them will urge that it is improved by the processes it undergoes, and the additions it acquires. They will affirm that by percolation through various inorganic substances it acquires traces of salts which are beneficial to the system; that by passage through chalk, it becomes charged with carbonic acid, and is sparkling and agreeable as a drink; also that the trace of organic matter it acquires is largely removed by oxidation as its rippling streams are agitated in contact with the atmosphere, &c. If it be true that the mineral additions which water acquires by percolation through various earths be beneficial or necessary, surely it is within the resources of science to provide them in the best proportion, instead of relying on the chance admixture, which must be uncertain in quantity and quality. And it must be better to have no organic matter to oxidize than to depend upon slow natural processes for removing it. The agreeable sparkling water which comes through the chalk brings with it more than an exhilarating gas: it brings insoluble salts which accumulate in the system, causing disease, agony, and death. These insoluble salts, accumulating in pipes and boilers, are common sources of explosion and great inconvenience, as well as of serious expense. In country districts where there is no public water supply, and pumps are depended upon for getting the water from shallow wells, fed by surface drainage, the case is worse still. The supply here is rain water filtering through all kinds of unnamed nastiness, of which typhoid and diphtheria are too frequently the result. It were a bootless task, however, to attempt to enter into detail of all the reasons why rain water in its original purity and cheapness should be preferred to that which is sophisticated and costly.

To photographers, Mr. Hibberd's pamphlet should be especially interesting. They require a great deal of pure water. And it is not too much to say that for lack of plenty of water, and for lack of water possessing the proper solvent power of soft or rain water, much of the fading which has made the art a bye-word is due. Every solution the photographer has to mix is better prepared with pure water than with the unknown compound known as "tap water," that is, water from the public supply. Distilled water largely used by the careful photographer is costly. Pure rain water will answer every purpose as well, and meet every want of the photographer.

"But how is rain water to be obtained pure?" many will cry. As it reaches mortals, it first washes the foul atmosphere of large towns; it next washes the dirty roof, and reaches the consumer charged with solutions of decaying leaves, bird droppings, soot, &c. This is true enough, and how to meet the difficulty is an important part of the aim of the pamphlet. The first shower that falls in a rainy period will, of course, wash the smoke-laden atmosphere and the house roofs of their accumulated dirt. This water will serve for garden use and other rough purposes. Mr. Hibberd shows there need be no difficulty in keeping the first showers and the subsequent rainfall separate. Vessels of proper capacity, receiving the first water and becoming full, may be made at once to act automatically in diverting the remaining supply to other reservoirs kept for the storage of pure water, which, after subsidence and filtration through a good filter, may furnish the supply described by Keats, which Mr. Hibberd adopts for the motto of his pamphlet—

"An endless fountain of immortal drink
Pouring into us from the heaven's brink."

If the thirty millions, or upwards, which form the population of this country, do not fairly deserve the character which Carlyle has given them of being "mostly fools," a revolution in the water supply must speedily follow the publication of this pamphlet.

THE GELATINE NEGATIVE PROCESS.

BY A. J. JARMAN.

IN the making of gelatine emulsion for sensitive dry plates, I have found that a great improvement is effected in the quality of the emulsion by employing gelatine of two different makes. I employ now half of Nelson's and half of Swinborne's, and by an improved method of drying can dry three gross of plates in four-and-a-half to five hours. So much success in the production of gelatine dry plates depends upon their being rapidly dried, and after a prolonged series of experiments, I cannot find any plan better than the slow method of emulsification. There is certainly something produced by the long continued emulsification in gelatine emulsion besides the change in colour of the silver bromide. There is undoubtedly some change in the gelatine which adds greatly to the sensitiveness; but what this change is, I am unable to say.

By using a strong solution of alum, *i.e.*, a saturated solution with one ounce of methylated spirit to the pint, the shadows clear up very nice indeed, and if intensification is needed by the negative being thin, use the following—

Mercury bichloride	60 grains
Water	4 ounces
Potass. iodide	140 grains
Water	4 ounces
Hypo-sulphite of soda	40 to 60 grains
Water	2 ounces

Mix the potass. iodide solution with the mercury solution, shake well, then add the hypo. Filter; and place the negative in this mixture. A few minutes will suffice to give the required density; wash well after this, and dry without heat.

I hope the above hints may be of use to those who are using gelatine plates; any information that I can give from experience upon the gelatine process I always shall, as it is of no use hiding one's light under a bushel. I may also say to those who have written to me for plates made by my process, that they will see by an advertisement in the present issue of the PHOTOGRAPHIC NEWS that I have entered upon the manufacture of them.

COPYING VIEWS FROM NATURE.

A SIMPLE and portable camera, for enabling inexperienced persons to take copies of views from nature, has been patented by Messrs. Kershaw, of Sheffield. It consists of a box having at one end a lens or lenses, and at the opposite end a sheet or pane of clear glass, on which latter a sheet of tracing paper or other transparent paper or material is held or secured. The view of the object to be copied is projected by the lens or lenses on to the glass, and traced by means of a pencil or other convenient instrument on the sheet of tracing paper or other material employed. When a single lens is used, the view of the object as projected upon the glass or traced upon the paper is in an inverted position, but by the employment of additional lens, as shown in the figure, the view of the object

is again inverted, so as to be projected and traced in its natural position.

When a box is used of the construction shown in the drawing, the parts thereof are so fitted as to admit of their being folded together for the convenience of carriage. The top is first removed, and the lens or lenses with the holder having been detached from the end, the latter is removed, as also the glass end, and these two last-mentioned parts are laid in the top, and secured therein by a button. The sides, which are hinged to the bottom, are then turned down in succession, and the two parts connected together by bayonet fastenings. The box may, however, be modified in construction according to circumstances. For example, the box may be made so as to be susceptible of construction and extension after the manner of an ordinary camera-obscura, in order to afford facilities for adjusting the focus, or it may be constructed in any other convenient manner.

An apparatus for enlarging or reducing drawings, for lithographic purposes, has been patented by Mr. H. A. Dufrene, of South Street, E.C., and consists of an improved machine for uniformly stretching the rubber sheets upon which the drawing has been placed for enlargement previous to transferring it to the stone. The apparatus is constructed of an extensible frame, on the sides of which the edges of the india-rubber are fixed by a suitable number of hooks. The bars of the frame are cylindrical and surrounded with spiral springs, stretching or contracting with frame, and drawing in their movement the hooks so as insure a uniform tension. Movement is given to the bars of the frame by means of four screws, each having a right-handed thread at one end, and a left-handed thread at the other end, so as to draw apart or towards one another, two and two, the bars of the frame. Two handles placed on two adjacent sides of the stands of the apparatus connect these screws, two and two, by means of an endless chain, and allow of separately moving two of the parallel bars, or the two others, or the four at once. A scale placed on the stand shows the exact measure of the enlargement or reduction.—*English Mechanic.*

ON GELATINO-BROMIDE OF SILVER.

BY DR. VAN MONCKHOVEN.*

Development of the Image.—The image can be developed either immediately, or several days after exposure; but by deferring the development too long it will probably happen that the effect of the light has diffused itself over the whole film, and the plate in consequence will be fogged. For developing gelatino-bromide plates two methods are recommended, the one by pyrogallie acid, the other by a salt of iron. The first of these has the greatest number of adherents, who assert that when this method is employed the exposure need not be so long. Dr. Van Monckhoven, however, speaking from personal experience, maintains a contrary opinion, and believes that by the development with iron both in the gelatino-bromide, and the wet collodion processes, the shortest exposures are rendered feasible. He also declares that the images developed by pyrogallie acid are dull, and have a very deceptive colour as regards intensity, rendering retouching very difficult, while those developed by a salt of iron are equal to the best negatives taken by the wet collodion process. Then again, a solution of pyrogallie acid stains the hands, and must be prepared afresh every time of using, whereas one of iron can be employed for developing a large number of plates without renewing.

The following is Dr. Van Monckhoven's preparation of the iron bath: into the first of two milk-saucepans, each holding about a litre, he puts 200 grammes of pure iron sulphate, and pours on it half a litre of boiling water, stirring it with a glass spatula until all the salt be dissolved. Into this solution is thrown 100 grammes of oxalic acid, and the mixture is again stirred until the crystals of acid have disappeared. Oxalate of iron is thus formed in the hot liquid,

and will be precipitated in about ten minutes; at the end of that time the clear supernatant fluid is decanted off, and the saucepan is again filled up with hot water; this is stirred, the salt again allowed to settle for ten minutes, and the clear fluid drawn off as before; the same operation is repeated four times. During this last washing 250 grammes of neutral—not the common—potassic oxalate is put in second saucepan and dissolved completely in three-quarter litre of boiling water. This solution is then poured over the ferrous oxalate prepared in the first saucepan, the whole is well stirred and poured into a litre flask, filling the flask if necessary to the top with water, and taking care that all the yellow ferrous oxalate goes into the flask. Lastly, about 100 grammes of iron wire in 15 centim. lengths are placed in the flask, and after the solution has got thoroughly cool, it can be used the next day. Before actually using, it is filtered into a long upright bath, with as little access of air as possible, so as to prevent the ferrous being converted into a ferric salt. If it be necessary to use a horizontal bath, the developing solution must be poured back again into the mother liquor after each development. Every night, or when the work of the day is over, the iron solution should be poured back into the flask, and the latter filled up with a saturated solution of neutral potassic oxalate. It is also best to plunge the flask at night in very hot water, so as to dissolve some of the crystallised oxalate that has settled at the bottom, and thus to prevent the liquid from deoxidising in contact with the metallic iron kept in the flask. In order to preserve the properties of the iron developer, the solution should be maintained at a temperature not lower than 15° C., otherwise the neutral oxalate will crystallise.

To understand the reason for all these precautions it must be remembered that the salt which develops the image is the ferrous oxalate, and that this salt is only slightly soluble in cold neutral potassic oxalate; it becomes, therefore, necessary to introduce fresh ferrous oxalate in proportion as it is eliminated. The flask above mentioned contains a large excess, quite enough for a week's continuous work; but if the potassic salt be allowed to crystallize, it imprisons the ferrous oxalate, and we have neither a solvent nor the dissolved substance. Hence all the various difficulties that will be met with in developing; but it is easy to obviate them. (1). Let there be several separate baths. (2). Keep a flask of solution which has lost its properties in hot water until it has arrived at the same temperature. (3). Prepare every three days a new bath of ferrous oxalate.

The formula for the bath is not, however, yet complete. A solution of 100 grammes of ammonium bromide must be prepared, and from 10 to 50 centims. of it added to every litre of the solution of ferrous oxalate. The exact quantity is determined by experiment, as will be shown further on.

To develop a plate in an upright bath plunge it in by a quick but continuous movement, and raise and lower it several times on the dipper. When the bath is horizontal the liquid in it must be kept in motion. If these precautions be not observed, a mass of greasy spots would appear on the film, caused by the gelatine repelling the water, these will form round transparent spots in the image. When the plate has remained in the bath for half a minute the high lights will make their appearance; in the course of a minute or a minute and a-half, the details in the shadows will show, and at the end of two, or sometimes three, minutes, the image will be completely developed, as may be seen by the black parts showing through the film at the back. The plate is then thoroughly washed under a tap, and fixed as described below; the washing is best effected with rain water.

Now, in working this process, beginners will be sure to meet with many failures and disappointments. Very often the blacks of the picture come out well, but with the appearance of the half-tones a change takes place in the colour of the plate; it begins to fog, and the fog eventually covers the whole and obliterates the image. This fogging

* Continued from page 590.

is due to the red glass of the window of the dark room being too light in tint, or to its joints not fitting closely, or, as is more often the case, it is caused by defects in the dark slide or in the camera. If these faults have been carefully corrected, make another test by taking a plate which has not been exposed at all, and immerse it in the iron bath; if there be still a fog it is owing to the plate having been prepared or dried in a place which is not proof against the penetration of light. But if it be still not due to the latter cause, add from 10 to 50 cubic centimetres of ammonium bromide solution to every litre of the bath, shake it well, and let it settle for a quarter of an hour. Then plunge an unexposed plate into it, and if there be still fog observable, it must be either in the dark room or the drying room that the cause must be sought. It will be found that the addition of iron bromide does not diminish the duration of exposure; but it increases that of development. On the other hand, the high lights of the plate will be perfectly white by reflected light, and in fixing the image will be quite clear and free from fog. When, with all these precautions, the emulsion is liable to fog, the only remedy is to give a double or triple length of exposure in the camera, and to arrest the development before the fogging appears.

At the outset it was mentioned that there is great difference between one emulsion and another, but with a little practice their relative degrees of sensitiveness are soon discovered. The greener and more grained they are at the edges of the plate, the more rapid they are. These quick working plates require greater care in development, and the addition of more ammonium bromide to the bath than the others.

(To be continued)

Correspondence.

THE MIRAGE PHOTOGRAPHS.

SIR,—Several times, within the last few months, mention has been made in your journal of a photograph taken at Tenby, which was supposed to exhibit the mirage of a gun-boat lying at the time off Pembroke Dockyard.

As it would have been a curious and important record, had the mark in the photograph in question really been the result of mirage, I thought it was worth while to examine the matter.

The photograph is one of Tenby Church spire, and an analysis of the perspective of the picture shows that if the focal length of the lens employed was about eight inches (probably not far from the truth), the axis of the lens must have been elevated about 30°.

The mark supposed to be the ship is near the top of the spire, and must have appeared at the camera to have an elevation of about 40°, and an angular width of about 5°. The photograph is taken from such a position that the outer angle of the staircase turret appears to coincide nearly with the centre line of the spire.

Now the staircase turret is at the S.W. corner of the tower, hence the camera must have been pointing N.E. nearly. Pembroke Dock bears about 9° N. of W. from Tenby, and is about eleven miles off.

If the gun-boat was between 150 and 200 feet long, she would subtend about 10' when viewed broadside on at a distance of eleven miles. But Captain Parkins, Captain-Superintendent of Pembroke Dockyard, informs me that about six p.m. on May the 5th (the time when the photograph was taken) the gun-boat lay with her head N.E., i.e., with her centre-line in the same azimuth as the axis of the lens.

These facts have only to be stated to show that the mark on the photograph cannot be due to the mirage of one of the gun-boats at Pembroke Docks; but in reality, the possibility of its being mirage at all is precluded by the great altitude (about 40°, as before stated) at which it appears. As far as

I know, no mirage is ever seen with more than 2° or 3° elevation above the horizon at most.

One of your correspondents on the subject, Mr. S. Withers, mentioned a curious mirage seen by him in the West Indies; this he was kind enough to inform me might have been, according to his recollection, about three times the sun's apparent diameter, or about 1½ degrees above the horizon.—

Yours, &c.,

ARNULPH MALLOCK.

Brampford Speke, nr. Exeter.

DEVELOPING GELATINE PLATES.

DEAR SIR,—Having seen Mr. J. Werge's non-actinic developing tray (which I consider very ingenious and useful), I thought it would not be out of place to let amateurs who, like myself, have not much time to spare, and develop their plates in the evening, know what I have used ever since I worked gelatine plates. I have constructed a dipping bath out of ruby glass, with an ebonite top lined with black velvet, and in which is fixed a silver dipper. This little piece of apparatus I find answers very satisfactory.—Yours truly,

JAMES STAMFORD.

P.S.—I may add that I use the ferrous oxalate developer, and use a caudle for a light.

THE PHOTOGRAPHIC CLUB.

SIR,—Referring to Mr. Cutchey's letter in answer to mine, there is no necessity for me to be a member of the two London Societies, because I have been for some years. The Parent Society (the father of the infant Photographic Club, no doubt) I seceded from after the president affair; the South London on account of the distance, and because the business did not have an all-absorbing interest for me. And I partly suspect the fact of the starting of the Photographic Club was because it was found the general business of the society did not come up to their ideas of what it should be, and the whole affair was stale and unprofitable. I merely offered what I did respecting the Photographic Club as suggestions—"without charge," or with the idea of filling any office attached to it. My suggestions presumably were right, or why did the committee act upon them?

If Mr. Cutchey had long been a member of the two London Societies he would have known I advocated discussion *en famille*, so that many matters would be talked over by members who would feel great diffidence in mounting a platform and holding forth for the first time; it's like standing on the banks of a river undressed, waiting for the resolve to plunge in. It wants some courage, especially if the "depth" is uncertain. The Photographic Club will arrange all this, I hope—*nous verrons*. Now, referring to "clique," surely Mr. C. was not an exhibitor at the Society's annual exhibition, but was, like me, an outsider looking on.

This reminds me of a good joke. An operator applied to a friend of mine, a photographer, for a situation, enumerating his different capabilities for out-door work, or, as he said, outside work, at which he was unapproachable—in fact, he was an exhibitor at the Society's Photographic Exhibition. Well, my friend, thinking he had got a good man, before finally engaging the party paid a visit to the Photographic Exhibition, and, after some searching in the catalogue and on the walls, he discovered one little miserable view. He was quite decided. The party called next day. "Well, sir," said he, "did you see my *outside* work?" "Yes," was the reply. "And what did you think of it?" said he. "Well, my opinion is," said my friend, "that you are a rank outsider, and you won't suit me." "Oh! but it was not hung right," said he. "You ought to be," said my friend. And the fellow went away, grumbling that he ought to have had a medal.

But I am digressing. I certainly did not understand it was finally settled that anyone could join the Photographic Club without being a member of one or other of the Societies. I read that it was proposed to be so, but it was referred to the committee. I am, therefore, happy to hear

their resolve, and for one appreciate their freetrade policy; and, in conclusion, I hope to find a proposer and a seconder for membership of the Photographic Club.—Yours respectfully,
JAMES SYRUS TULLEY.

[We have cut out some good joking from the commencement of our correspondent's letter, because of the probable misconstruction and possible annoyance which might result.—ED.]

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The annual meeting of this Society was held on the evening of Thursday, December 4th, the Rev. F. F. STATHAM, M.A., in the chair.

The minutes of a preceding meeting having been read and confirmed, the following gentlemen were elected members of the Society:—Messrs. Rogers, Ackland, and Maxwell.

The meeting then proceeded to the election of officers, and after the passing of a resolution to the effect that, in future, the number of vice-presidents be limited to six, the following officers were elected:—

President—F. F. Statham, M.A., F.G.S.

Vice-Presidents—G. Wharton Simpson, M.A., F.S.A., Jabez Hughes, Frank Howard, W. Brooks, P. Mawdsley, and E. Cocking.

Committee—Messrs. Adkins, Bolas, Bolton, Cutchey, Cowan, Dunmore, Warnerke, and York.

Hon. Treasurer—F. A. Bridge.

Secretary—H. Garrett Cocking.

The SECRETARY then read the following report:—

Secretary's Report.

"In presenting the annual report of the South London Photographic Society for the year 1879 your committee have to congratulate the members upon the increased vitality shown during the past year. A step has been taken in the right direction by some of the younger members coming forward to read papers and to show new apparatus, &c. One of the principal matters of the past session has been the adoption of Mr. E. Dunmore's scheme for an artistic competition (for the members only) to be held monthly. Your committee hope that this competition will not only advance the prestige of the Society, but also tend to the promulgation of artistic culture amongst the members.

"The annual Lantern Exhibition for the display of slides by members and others was held at the January meeting, when Mr. F. York exhibited slides taken by himself of the Paris Exhibition, a description being given by Mr. McCall. The eighth annual Technical Exhibition was held in November, and your committee are pleased to state that it was a great success, both as to the number of visitors and the quantity of appliances shown.

"The following papers have been read during the session:—

"'Gelatine Plates in the Studio,' by Mr. J. T. Hazard; 'Demonstration of his Platinum Process,' by Mr. W. Willis, Jun.; 'Imitation Porcelain Transparencies,' by Mr. W. J. Auckorn; 'Artificial Lighting,' by Mr. R. V. Harman; 'Finance,' by Mr. F. A. Bridge; 'How To Take a Negative by Artificial Light for 1½d.,' by Mr. Brittlebank; 'Artificial Light,' by Mr. Archer Clarke; 'Continuance of Action of Light in Carbon Printing,' by Mr. E. Foxlee; 'Reflectors and How to Make Them,' by Mr. W. Harrison; 'Future Usefulness of the Society,' by Mr. Brittlebank; 'Experiences with Gelatine Plates,' by Mr. H. Garrett Cocking; 'Photographic Signs of the Times,' by Mr. W. Cobb; 'Artistic Competition,' by Mr. E. Dunmore; 'Improved Photographic Apparatus,' by Mr. L. Warnerke; 'Hints on Competition,' by Mr. E. Cocking; 'Clarification of Gelatinous Solutions,' by Mr. T. Bolas.

"Photographic apparatus, &c., have been shown by the following gentlemen:—Messrs. Bridge, Ayres, Harrison, Henry, Bolton, Wratten and Wainwright, York, Cowan, Warnerke, Stringfellow, Brooks, Ackland, Clarke, Werge, Lane, Edwards, Jones, Heuderson, and Wilmer.

"In conclusion, your committee trust that with the important increase in the number of members, and the revived interest shown in the matters connected with the Society, the ensuing session will be one of marked activity, and the result great usefulness to its members."

The rules for the art competition will appear in our next.

The TREASURER'S report was then read, and showed, instead

of a deficit, as on some former occasions, a balance in hand from last year of £3 9s. 2d., and with the subscriptions in advance for the coming year, a balance of £14 9s. 8d., a state of things on which he congratulated the Society.

Mr. BOLAS then read a paper on the "Clarification of Gelatinous Solutions" (see page 591), and demonstrated the method.

After some conversation,

Mr. E. COCKING read a paper on "Some Hints on Composition" (see page 590).

The PRESIDENT made some observations on the importance of a consideration of the laws of composition in relation to the proposed artistic competitions.

After votes of thanks to the president, treasurer, and other officers, the proceedings terminated.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting was held at the Museum, Queen's Road, on Wednesday, 3rd Decmber, Mr. T. DAVEY in the chair.

The minutes having been confirmed,

Mr. H. A. H. DANIEL said that at the last meeting he gave notice of a proposition he was about to make, viz., that from that date all ordinary members joining the Association shall pay an entrance fee of one guinea.

The CHAIRMAN asked why Mr. Daniel considered an entrance fee necessary; he asked, so that the reasons might be gone into and discussed.

Mr. DANIEL replied that one reason was, that every year the balance of the books of the Association was a much closer thing than he considered should be, it being quite an uncertain thing whether the balance was in favour of the Association, or due to the Treasurer. Secondly, there were occasionally purchases the Association would like to make, such as a portfolio for contributed prints, &c.; and whereas he did not doubt that the members would, if asked, readily give donations for any special object of that kind, still he did not consider that special "whips" now and again were satisfactory or good for any society.

Mr. WALTER STEPHENS said he thought that in scientific and art societies the entrance fee and subscription were identical as to amount, whereas a guinea would be double the subscription; he presumed also that the corresponding members would not be included in the resolution.

Mr. E. BRIGHTMAN, as Treasurer, corroborated Mr. Daniel's assertion that sometimes there was a balance of a few pounds due to him, but that it was made up at the following meeting when the subscriptions were paid. He bore out Mr. Stephen's remark as to the amount of the entrance fee and subscription being the same, by instancing the Loudon Society.

The CHAIRMAN asked Mr. Daniel if he would alter the amount of entrance fee in his resolution from one guinea to half a guinea.

Mr. DANIEL replied that if that were the general feeling, he would be pleased to do so, and requested that the resolution be read so. He noted Mr. Brightman's remark as to the balance due to him being made up when the subscriptions were paid, but as that was paying a past year's deficit from a new-year's income, he held that it was not sound financing, and thought it was all the stronger reason for an entrance fee being instituted.

The CHAIRMAN then put Mr. Daniel's proposition to the meeting, it having been seconded by Mr. Brightman, and it was carried unanimously.

The HON. SECRETARY announced that the remaining business of the evening was the exhibition and discussion upon the negatives and prints resulting from the out-door meetings.

The CHAIRMAN said he had been amusing himself by some attempts at making lantern slides on gelatine sheets, and for first attempts thought he had been tolerably successful; he hauded a few round for exhibition. From their appearance the chief difficulty seemed to be that of causing the slides to dry perfectly flat, and not puckered. Apart from this, the Chairman was congratulated on such successful "first attempts."

Mr. BRIGHTMAN stated that he had one or two prepared by Mr. Woodbury, and they were perfectly even and flat, and showed very well in the lantern.

Mr. DANIEL also possessed one prepared by that gentleman, but did not find it had preserved a perfectly flat appearance, but he believed Mr. Woodbury had much improved on those, and he should be very much interested in knowing what Mr.

Woodbury had done in the matter, and knew the members would also feel pleasure in hearing anything that might be communicated on the subject.

Mr. BRIGHTMAN exhibited some gelatine negatives taken on Wratten and Waiuwright's plates, and, although pleased with the process, he said he could not say he was altogether satisfied with it. He did not find it possible to give so full an exposure to the foreground and dark parts of a picture, without spoiling the distance, as we could with the wet process.

The Hon. SECRETARY then handed to each member present the following final and complete list of medals and conditions for the International Exhibition in Bristol next year, and was pleased to be able to state that already applications were rapidly coming in for full particulars, also intimations of exhibits.

"Bristol and West of England Amateur Photographic Association International Exhibition."

"The Council of the above Association beg to announce that they intend to hold an Exhibition of Photographs, Photographic Apparatus, and Appliances in the Galleries of the Academy of Arts, Queen's Road, Clifton, Bristol, to be opened on Friday, 17th December, 1880, continuing open till Saturday, 15th January, 1881.

"Apart from photographs for competition, the Council will esteem it a favour if those who have any interesting examples of the history and progress of photography, will kindly lend them for exhibition.

"All pictures, apparatus, and contributions of any kind will be insured at the expense of the Association.

"Special care will be bestowed on the hanging, so that all pictures shall, as far as possible, be done justice to, to facilitate which, the whole of the extensive galleries above referred to have been retained.

"Conditions.—There will be no charge for wall space; but there will be a small universal entrance fee of five shillings to be paid by each exhibitor in competition.

"All pictures for exhibition (except as below stated) must be sent mounted and framed, with the artist's name and address on the back; the titles of the subjects and process by which produced may be neatly affixed to the front of the pictures. On no consideration will the name or address of the artist be permitted on the front, as such will appear in the catalogue, and no pictures in Oxford frames will be admitted.

"Pictures from India and the Colonies may be sent by post, unmounted, and the Council will undertake to have them mounted at the cost of the exhibitor, such expenses to be deducted from the proceeds of the sale of the pictures. Nevertheless, where possible, the Council would recommend exhibitors sending their pictures ready framed, according to their own tastes. All unmounted pictures must be delivered by November 1st. The most direct route from America is from New York by the 'Great Western Steamship Line' direct to Bristol, with which Company special rates for exhibitor's packages have been made.

"The Council undertake to unpack, repack, and return all exhibits remaining unsold; all carriage must be paid by the exhibitor. Every care will be taken of the exhibits, but at the same time the Council will not hold themselves liable for any untoward accident that may occur, with the exception of loss by fire, which is specially provided for.

"The Council will undertake the sale of exhibited pictures at the usual commission of ten per cent.

"Photographs coloured by hand will be excluded from competition.

"The hanging committee will reserve the power of rejecting any pictures.

"Each exhibitor must fill up the annexed form A, and forward it to the Hon. Sec. not later than November 1st.

"All pictures intended for exhibition must be sent carriage paid, to arrive not later than December 1st, addressed 'International Photographic Exhibition, Academy of Arts, Clifton, Bristol,' form B being sent as a letter of advice.

The following is the list of the medals which will be awarded for the best and second best pictures in the various classes, and to be decided on the opinions of five gentlemen, being two eminent artists and three well-known photographers, three of the judges being outside the Association.

"1. A Gold Medal for the picture or series of pictures which, in the opinion of the judges, possesses the highest degree of merit, irrespective of size or subject.

"2. One Silver and one Bronze Medal for the best and second best landscape or series of landscapes of 8½ by 6½ or under.

"3. One Silver and one Bronze Medal for the best and second best landscape or series of landscapes above 8½ by 6½.

"4. One Silver and one Bronze Medal for the best and second best portrait or series of portraits of 8½ by 6½ or under.

"5. One Silver and one Bronze Medal for the best and second best portrait or series of portraits above 8½ by 6½.

"6. One Silver and one Bronze Medal for the best and second best genre picture.

"7. One Silver Medal for the best enlargement of any subject and by any process, provided it be the work of the exhibitor.

"8. One Bronze Medal for the best transparency or series of transparencies.

"9. Four Bronze Medals, to be awarded according to the discretion of the judges, for improved apparatus, materials, processes, or other meritorious productions.

All communications must be addressed to the Honorary Secretary, H. A. H. DANIEL, Avonmead, Leigh Road, Clifton, Bristol."

After a little further discussion the meeting stood adjourned, till June 7th.

EDINBURGH PHOTOGRAPHIC SOCIETY.

The second ordinary meeting of this society was held at 5, St Andrew Square, on the evening of Wednesday, the 3rd December, Mr. W. H. DAVIES in the chair. There was a large attendance.

After the Secretary had read the minutes of the past annual meeting, a council meeting, and several committee meetings, which were approved of, the following were unanimously elected ordinary members of the society:—Messrs. James Elliot, Thomas Ross, Thomas Kelly, W. D. McCombie, Alexander Birchan, George Murray, William Rankin, Patrick F. Sinclair, James L. Strang, and Miss C. Archibald.

A recommendation by the council that there be a presentation print for the current session was unanimously approved of.

Dr. T. DRINKWATER then read a paper entitled "A Few Reasons why Photographers should Study Practical Chemistry" (see page 592). At its conclusion—

Dr. THOMSON said he had to thank Dr. Drinkwater for his paper recommending the photographer to make himself acquainted with the general principles of chemistry, and to ground himself more thoroughly in that department of the science which had a bearing on his own profession; at the same time he should acquire manipulative dexterity, in order that when any new process was introduced he might with confidence put it to the test of experiment. Such a paper was much needed, and would produce a beneficial effect, no doubt, on many of the members. It was the want of the little amount of scientific knowledge that had retarded the progress of photography. Most professional photographers, had they been more conversant with chemical pursuits, would by this time have been able to lay aside their silver baths, and depend entirely on their dry gelatine plates for producing as good, if not better, work than they had been doing. Of course, a great deal of experience was required in the proper development of the dry plate; but when this had been studied, and practised for a much shorter time than was necessary to give confidence and success in the wet process, the result would be all that could be wished. Besides, with his knowledge of chemistry, and possessing dexterity in manipulation, he would have no difficulty in preparing his own plates, and thus avoid the heavy expense of buying them. Five shillings would make sixteen ounces of emulsion, and that quantity would readily coat eight dozen of full-plate size.

Mr. CRAIG-CHRISTIE remarked that no words could be sufficiently forcible to impress the importance of a knowledge of chemistry to the photographer, who was constantly engaged in delicate chemical manipulations. A practical acquaintance with the ordinary routine of a chemical laboratory would enable him to rationally combat many of the difficulties that are constantly arising, and thus avoid the sudden breakdowns which occur with the ordinary mechanical worker. He would also be enabled to grasp at once any new departure in the various manipulations, and his knowledge would readily supply him with chemical equivalents that might be needed in an emergency.

Mr. THOMAS PRINGLE had derived a great deal of information from attending a class of analytical chemistry. Such information was especially useful at that time, when everybody of note was adopting the new gelatine process, the manipulations of which were entirely different from those of wet collodion. There were many different developers recommended, and most likely the best had yet to be found. Wet collodion had been tried and found wanting in those very points where gelatine was peculiarly efficient.

Mr. JOHN ANNAN said he trusted a practical application would be made of the valuable paper of Dr. Drinkwater, and suggested that the council should take the subject into consideration, and bring up a report and recommendation as to the best means to be carried out for securing so desirable an object. Some years ago he had made a proposal that the Society should secure rooms fitted with suitable appliances, where members could meet and test the various new processes and modifications of old ones that were continually cropping up, so that their value might be ascertained and adapted to every-day practical work. Having such rooms, a class for the study of chemistry would be less difficult to organize and more likely to succeed, being linked on to what concerns the professional photographer's daily work. They were very much indebted to amateurs and experimentalists, who find their daily pleasure rather than pecuniary profit in their experiments, and it would be well if the professional and amateur were more frequently brought into contact with the view of overcoming technical difficulties and developing new processes. Such meetings would stimulate progress in the art, and if their Society possessed suitable rooms its usefulness would be most materially increased.

Mr. ALEXANDER MATHISON next exhibited a collection of platinotype prints from a number of his own choice negatives. In doing so he explained that they were the first and only examples of the process he had ever produced, and paid a high tribute to the extreme simplicity and certainty of the manipulations, stating that he had not had a single failure.

Mr. W. T. BASHFORD drew attention to the rich, velvety blacks and the general warmth of tone that prevailed in many of the prints, pointing out that, in the examples on the table, the thinner negatives appeared to produce the warmest tones.

The CHAIRMAN directed attention to the capacity of the process for rendering truthfully strong contrasts when in juxtaposition, noticing as a remarkable example the purity and delicate detail of the white linen cap worn by an old fishwife standing in an open doorway, the latter being an intense black with a rich, juicy transparency.

Mr. J. M. TURNBULL, after expressing his unqualified admiration of the prints on the table, said that, in his opinion, platinotype was one of the processes that would materially affect the future of photography. He pointed out how slow photographers as a body were to take advantage of any new process. In the early years of photography, the bath process itself had to fight its way into notice. For many years the beautiful collodio-bromide process was only worked by a few individuals, and even now many were unacquainted with it. For years the carbon process languished ere it took any recognised position. Again, how tardy had the gelatine process been of coming to the front. After hanging fire for years, it was only now beginning to work its way into general notice. Photographers had long sighed after an instantaneous process; they had long had one within their reach, but, until recently, had failed to recognise it. In the same manner they had urgently desired a permanent printing process which, without the manifest disadvantages of pigment printing, should be strictly permanent, and simple and certain in its manipulations. The platinum process supplied all these requirements, but yet, up to the present, it had not taken the position which it certainly deserved. The manipulations were simple in the extreme, not the least of which was that the printing could be watched as it progressed; while the results, for certain classes of work, were simply unapproachable by any known process. Mr. Willis's platinotype had been the subject of very full demonstration in that room some two years ago, by Mr. Rodgers, of St. Andrew's, and specimens by it had been brought up, exhibited, and universally admired from time to time, and he considered it one of the great duties of a society such as their's to bring up such a matter again and again, until its great merits were fully recognised.

A hearty vote of thanks to Dr. Drinkwater, Mr. Mathison, and the Chairman terminated the proceedings.

Talk in the Studio.

A NEW NOVEL BY MR. BADEN PRITCHARD.—We are glad to hear that Mr. Baden Pritchard, whose name is so well known in the photographic world, is engaged in writing another three volume novel. The first chapters appear this week in *One and All*, under the title of "Georgo Vanbrugh's Mistake."

To Correspondents.

THE YEAR-BOOK OF PHOTOGRAPHY, 1880. In order to facilitate our labours in preparing the YEAR-BOOK OF PHOTOGRAPHY for next year, we shall be greatly obliged to those of our readers who can favour us with brief practical papers on subjects arising in their experience, so that our annual may be, as it is designed, a complete record of the progress of the year, and a trustworthy practical guide for the future.

T. BROWN informs us that he prefers iron to pyro for development, and asks us to give him a formula for iron developer which will give rich vigorous images on opal. Iron is undoubtedly a more pleasant and convenient developer than pyrogallic acid; but for some purposes it is not so good as the pyro. Developing on lion prints on opal or plain glass is one of those purposes for which iron is inferior to pyro development. Iron gives a grey metallic image, whilst pyro gives a warmer and more organic image, admitting more readily of toning, and having a richer and more brilliant effect by reflected light. If our correspondent be still anxious to try iron, let him make a developer with 12 grains of the protosulphate of iron and 30 minims of acetic acid to an ounce of water.

O. J. ELLIS.—The description you give of the negative from a plate of your own preparing shows it to be fogged, and if you gave it, as you state, the same exposure as a wet plate, the fog is easily accounted for, as it must be seriously over-exposed. A gelatine plate, as a rule, will not require more than a fifth part of the exposure required by wet collodion; in some cases we have seen good results produced by one-fiftieth of the exposure of a wet plate. We cannot undertake to say which is the best method of preparing gelatine plates. Some very able workers endorse the method described by Dr. Van Monckhoven in his paper before the French Society. Our volume for the past year is nearly full of discussion on the subject, and our forthcoming YEAR-BOOK will contain an ample summary of the most important facts and experiences.

M. F. R.—If the exposure is right, the use of a large proportion of pyrogallic acid will give you sufficient intensity. Remember that the colour is non-actinic, and that a negative which looks thin will often be found to possess sufficient printing density. There are various modes of intensifying gelatine negatives. It may be done with silver and pyrogallic acid, or, as some prefer, with iodide of mercury.

L. G.—There is no advantage in using the negative bath very strong; 40 grains to the ounce of water is the extreme limit of strength which can be used with advantage. As a rule, we should say 30 grains in summer and 35 in winter answers well. It is wise to use a large quantity of solution in the bath. A small bath and small quantity of silver solution are undesirable, as the solution in such case soon gets out of order, and works with uncertainty. Do not often filter. Use a dipper which does not permit the plate to go to the bottom of the bath, and frequently remove floating acum from the surface of the solution—always, in fact, before commencing work.

A WOULD-BE ARTIST.—The rules of composition, and of light and shade, so far as definite rules can be laid down for pictorial effect, are all defined and published. You will find full information on the subject in Mr. Robinson's work on "Pictorial Effect in Photography." A knowledge of such rules is essential to an artist, and will materially aid him in producing good work; but an instinctive perception of beauty is also a necessary pre-requisite. The desire to produce artistic work is often an indication of the existence of the latent power which may be developed by study, observation, and effort.

F. R. S.—Daguerreotypes were occasionally tinted by applying suitable colours in a state of very fine powder. Any touch of water colour to such a delicate surface was destructive. 2. Nicéphore Niepce and Daguerre worked in different lines and with different materials. The sensitive agent chiefly used by Niepce was asphalt, whilst the triumph of Daguerre was secured with iodide of silver. 3. The photography of the day is essentially of English origin. To Talbot's labours the production of negatives and multiplication of prints was due. The photographic properties of bichromate were discovered in England, and gelatine plates are due to England. Germany has done little in photographic discovery, and America no more, but both countries produce very fine work.

F. H.—The chief fault in the photographs sent is due to imperfect lighting. The sitter should be lighted by a strong light from one direction, instead of being flooded uniformly with diffused light. If you are compelled to work in the open air, you must use screens, so as to get the lighting something like that of a studio. Screen one side of the sitter and overhead. There is also a tendency to fog. Use an older sample of collodion, and a weaker solution of iron with more acid. Let us know the result.

W. B. C.—There is an excellent little book on the magic lantern by Mr. Chadwick, which will give you the information; and another good one published by the Stereoscopic Company. Several correspondents in our next.

The Photographic News, December 19, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PROFESSOR HUXLEY ON TECHNICAL EDUCATION—A STEAM BURNISHER—CHRISTMAS CARDS.

Professor Huxley on Technical Education.—Professor Huxley has lately been doing good service in calling attention to the absence of technical education now-a-days. Since it is no longer the custom to serve apprenticeships, the younger generation has a difficulty in receiving a technical education, for the trades that require such apprenticeship are daily becoming fewer. For this reason, while we now make it a *sine qua non* with every girl and boy that they should possess book knowledge, technical education receives little consideration. This, Professor Huxley considers a dire mistake, and many of our readers will agree with him. It is often of the greatest use to a lad to know something of practical mechanics, and to be able to handle tools with address; he never knows till after life how valuable such knowledge may be to him. Thus, many a photographer, for instance, who can ply a chisel and saw, will have congratulated himself for having familiarised himself with tools when a lad, for he has no need to go to a carpenter or cabinet-maker to drive a screw or dovetail a box. It was the custom till very lately—it may be so still, for aught we know—for German princes in a reigning family to pay particular attention to technical education, not merely for the purpose of being able to help themselves occasionally, but in case they might, by some unlucky turn of fortune's wheel, find themselves in the predicament of having to earn their own living. The idea has something romantic about it—the possibility that someday, perhaps, the prince may have to turn peasant—but it is none the less a common-sense view of matters. The reigning Grand Duke of Saxe-Weimar is, if we remember rightly, a turner or cabinet-maker, and enjoys the reputation of being particularly clever with the lathe. He, as well as his august brethren, were taught a handicraft by competent masters, and were required to go on with their mechanical education at the same time as they pursued book studies. Professor Huxley wants something of the sort to be followed in the ordinary education of our boys at home. The City Companies have plenty of money for the purpose, and since apprentices have almost ceased to exist, so far as City trades are concerned, he argues that no better use than that can be made of the money. Professor Huxley proposes the establishment throughout the country of institutions similar to the *Ecole des Arts et Metiers* in France, and the *Polytechnicum* in Zurich, or of the nature of the Royal Industrial College at Berlin, where our friend Dr. Hermann Vogel, it will be remembered, occupies a chair as professor of chemistry and photography. In London, the wealthy Guilds, as we know, were established as much to look after the good training of apprentices as anything else, and a part of their rewards, therefore, might well be devoted to fostering technical education. In fact, Professor Huxley goes farther, and, as far as London was concerned, expressed a belief that "it would be a scandal and a robbery if a single shilling were asked for out of the general revenues of the country for technical education. The City of London Guilds possessed enormous wealth, which had been left to them for the benefit of the trades they represent. If the people did not insist," said Professor Huxley, "on the wealth being applied to its proper purpose, they deserved to be taxed down to their shoes. It would be well if those who had charge of these matters in the City of London would understand that they were morally bound to do this work for the country, and he hoped, if they continued to neglect the obligation, they would be legally compelled to do it." These are strong words to use, no doubt, but we may be sure that they are earnest and well-meant. Something must be done to supply the place of the technical education which our forefathers re-

ceived in their apprenticeship, otherwise a time will come when book-learning, and that alone, will be acquired. The photographer, more perhaps than most people, is interested in the matter, for with him the value of a technical education is paramount. There were plenty of defects, no doubt, in the old system of apprenticing youths to a trade, but the system had its advantages notwithstanding, and we ought to find a way to compensate us for those advantages. Mr. Huxley, we are glad to hear, tells us that the City Guilds have been to consult him on the subject, and hence we may have a chance of seeing some of his practical views carried out. He would not have the present teaching of the School Boards interfered with, as the boys do not have too much of it at present. An extension of the kindergarten system, in which infants are taught to use their hands quite as much as their brains, by the imposition of simple mechanical tasks, and which includes the use of tools and the knowledge of elementary mechanics, would be a good beginning, doubtless, for he could not but think that the evil of not giving hard-work in the elementary schools was, after all, very great. Although it was a great thing, he said, to make skilled workmen, yet it was more important still to make intelligent men. The City Guilds have already taken steps for the teaching of chemistry and physics, and a professor to that end has already been appointed; but it is not so much a scientific as technical training of which our youth stand in need, as Professor Huxley very forcibly points out.

A Steam Burnisher.—We had the pleasure the other day to witness the performance of a steam burnisher, which, if it is not too costly a piece of apparatus, should be useful to photographers at large. The apparatus in question was constructed by Mr. John Calder, of Plumstead, who seemed to have given the subject considerable attention, and has certainly devised a very effective instrument. The burnisher is of steel, and has a fine polished surface some five inches broad and twelve inches long; it is hollow, and, steam being passed into it, the metal is maintained at a high temperature, while there is at the same time no chance of an injury arising to the mounted photograph by over-heating. The supply of steam is generated from a little boiler, which is maintained at a proper heat by a Bunsen burner. The boiler is simply connected with the burnisher by a piece of flexible tubing, which may of course be more or less long according to circumstances. The burnisher when at work is attached to an ordinary rolliug-press, and the pictures are made to scrape against the highly-heated and highly-polished steel surface. The only drawback, to our mind, was the price, which for a twelve-inch burnisher was said to be £1; but in a large establishment, probably, the cost would not be of much importance. The steam burnisher certainly does its work well.

Christmas Cards.—At last photographers are getting alive to the production of Christmas cards, and there is something else on sale at the stationers' besides pictures of snowed-up cottages with the everlasting robin on the roof. If people are to send pictorial cards to one another at Christmas time, it is desirable that the missives should present some little variation, especially as nowadays purchasers spend a good deal of money on such trifles. To pay sixpence or a shilling a-piece for Christmas cards is no unusual occurrence, and we may be quite sure that anything good and new in the way of these festive pictures will find a ready sale. One of the most charming photographs we have seen is that of a yacht caught in full sail, "A prosperous voyage" being written underneath. The card is more suited for New Year than Christmas, but is a happy embodiment of hope in the future. Little summer landscapes, of which many may be seen on the new Christmas cards, form likewise pleasant missives, for it is not unwelcome to be reminded of warm sunshine and bowery foliage at this time of the year. Photographers may rely upon it that any happy notions they may put forward in this way will be eagerly welcomed by the public at this season of the year.

ON GELATINO-BROMIDE OF SILVER.

BY DR. VAN MONCKHOVEN.*

Development with Pyrogallic Acid.—Herr Obernetter, of Munich, who has practised the gelatino-bromide process with great success, prefers the pyrogallic acid developer to that of iron oxalate. He prepares first two solutions, the first of 1 part potassium bromide in 10 parts water; the other of 1 part pyrogallic acid in 10 parts alcohol. These solutions are kept in flasks provided with pipettes graduated to contain cub. centimetres. Besides these he has a pure and concentrated solution of ammonia in a dropping bottle.

To develop the plate (without first immersing it in water) it is placed flat in a porcelain dish containing a mixture of—

Bromide solution	2 cub. centim.
Pyrogallic acid	4 „
Water	250 „
Ammonia	10 drops

The constituents being added in the order here indicated. At the end of half a minute, the deep black parts ought to appear; if they appear before that time, 5 to 10 cub. centim. of the bromide should be added; if not in that time, 5 or 10 drops of ammonia—not on the image, but at a corner of the dish to which the contents are collected by inclining it. In this way an under or over exposed plate may be corrected.

The developer is allowed to act until the required degree of intensity has been attained, bearing in mind that this intensity will be diminished by fixing. To judge whether the plate has been sufficiently developed, take it out of the bath, and look at it by transmitted light. Afterwards the plate is thoroughly washed in water, and then fixed.

Fixing the Image.—This operation must be carried on in the dark, and is effected by means of a 15 per cent. solution of sodium hyposulphite. The process of fixing takes a longer time in proportion as the film is greener and more grained. It is not so simple an operation as in the wet collodion process, on account of the hyposulphite solution being liable to turn a dirty yellow colour (owing to traces of iron oxalate retained by the gelatine) with which it stains the film. For this reason, a considerable quantity of the fixing solution should be prepared beforehand, so as to replace any which may be observed to discolour. A concentrated solution of hyposulphite may not be employed, or blisters in the gelatine film will be the immediate result.

After fixing, as well as after developing, the plate must be thoroughly washed. The best way to effect this is to hold it under a tap of spring water for about half a minute, then to let it lie in a dish full of water for at least a quarter of an hour, and finally to rinse it a second time for a few seconds under the tap. Without taking this precaution, the image will pale under the subsequent operation of intensifying, or, if it be not necessary to intensify, the varnish with which it is afterwards protected will split off again. The film is sometimes found to frill or to detach itself from the plate either during development or after washing and fixing; to avoid this inconvenience, plunge the plate before development in a solution of chrome alum (10 grammes to the litre), then wash it in water for some seconds, and finally immerse it in the iron bath.

Intensifying the Image.—Some persons recommend pyrogallic acid and silver nitrate for intensifying the gelatino-bromide plate, but, in consequence of the silver combining with the gelatine, this gives rise to a deep red veil. Others use mercury bichloride dissolved in potassium iodide, but this causes the plates in a short time to turn the colour of chrome yellow. The following method will be found to answer well:—Reduce to powder, in a mortar, 20 grammes of mercury bichloride, dissolve it in a litre of distilled water, and throw in 20 grammes of potassium bromide and stir till dissolved. Again, dissolve separately 20 grammes of silver

nitrate, and 20 grammes of pure crystallised* potassium cyanide each in half a litre of distilled water; mix the two, and a light precipitate of silver cyanide will be found to settle at the bottom of the flask, and should be allowed to remain there.

The operation of intensifying may take place either when the plate is dry, or while it is still wet from washing after the fixing; in the former case it must be dipped for half a minute in water. First lay the plate in an open dish full of the mercury bichloride solution, and leave it there for a length of time proportional to the intensity required. The extreme limit has been reached when the plate becomes white all over. Then wash it well under a tap of spring water. Now plunge it into the second solution; if it has been kept only a short time in the mercurial bath it must be left only for a few seconds in the cyanide solution, but it may be allowed to remain a little longer if its immersion in the bichloride of mercury has been a more extended one. In any case the white colour produced in the mercurial bath will disappear, which can be well seen on examining the back of the plate. On no account may the plate be left too long in the silver cyanide, for the latter reacts in its turn on the black parts of the picture, and reduces their intensity.

Finally, the plate is again thoroughly washed and then dried. It may not be passed again through the hyposulphite solution, for that would destroy the intensity of the image altogether. The successive action of the mercury chloride and of the silver cyanide is to produce in the deep shadows of the picture a violet silver chloride which is not affected by light. The effect of this intensification is simply superb—quite equal to that of wet collodion plates.

Retouching and Varnishing.—Some photographers retouch the plates before applying the varnish; they find that the mat surface of the gelatine film lends itself easily to retouching either with the pencil or the stump. Others varnish the plates before retouching. As regards varnishing, it is effected in the same way as with collodion plates, care only being taken not to apply the varnish until all trace of moisture has been removed from the gelatine by exposing the plate to a gentle heat.

SOMETHING ABOUT SKY-LIGHTS.

BY O. W. OSBORN.†

THAT part of a photograph gallery which should receive the most attention, and be conducted in the best manner and on the most scientific principles, is the sky-light. Yet, notwithstanding the many hints and suggestions which have been offered through the medium of the practical and other journals pertaining to our art, the great mass of photographers in this country are using lights which are so defective and illy constructed as to render it impossible for any, save the most skilful workman, to produce even passable work. I agree with Mr. Inglis, of Montreal, Canada, whose article on lighting appeared in the June *Practical*, that “the large top-lights that are now so common in nearly every gallery, as well as a big reflector, are abundantly sufficient to make photographic art little more than a caricature.” I do not advocate the use of as much side-light as can frequently be found in a great many galleries, for the reason that, when a picture is perfectly lighted, the light should proceed from an opening at the top of the side-light, and at the lowest part of the sky-light, and the sitter placed as far from the side-light as the height of the same, or a little farther would do no harm, in order to secure the necessary angle of light.

A front top-light, proceeding from an oblique direction, is the best which can be employed where the highest class of work is attempted to be done. A small light is always best for single figures and bust pictures, while a large light is essential for groups. I never could see the policy

* Continued from page 597.

* Note that fused potassium cyanide will not answer the purpose.
† *St. Louis Practical Photographer.*

of putting a side-light in an operating room which would reach to within eight or ten inches of the floor, and then be compelled to completely stop out three or four feet of the lower part, in order to secure artistic work. No light should be admitted through the side-light that does not proceed from a point above the level of the sitter's head. Nothing could be worse than to open the top-light and close all but the lower part of the side-light. Yet I have seen that method attempted by photographers who enjoy a moderate local reputation. To avoid cross-lights, it is imperative that the effective bundle of rays which illuminate the head of the sitter proceed from a point about forty-five degrees from the perpendicular and from a few feet in front. Curtains, or more properly screens, should be placed upon both top and side-lights, so that as much or as little light may be admitted as is thought necessary. In the arrangement of the screens, both overhead and on the side, care should be exercised that they be placed on rollers—the top ones fastened at the highest point of the skylight, and those on the side should be fastened at the point nearest the floor. An arrangement of screens after the above fashion is the most rational and simple of all, inasmuch as they can be made to perform all the functions required of such devices.

In case it is required to make single heads under a very large, high light, I would recommend that they build an arrangement inside of the operating room like this:—Procure four pieces of pine about seven feet long and three-fourths of an inch thick by two inches wide; have them joined at the corners, making a square frame, over which fine wires may be drawn, to form an almost invisible support for the white tissue paper with which it is covered. The entire surface must be covered, except about two feet square in the centre, which is left bare. Suspend this arrangement over the head of your sitter by means of three cords attached to the wood work of the top-light, and by placing it three or four feet above the head of your sitter, the ill effects of a too large top-light can be almost entirely overcome. By moving this head-screen in different directions, either to one side or the other, a great many beautiful effects of light can be obtained. To produce brilliant lighting, it is necessary to have the light come through a comparatively small opening in the lower part of the top-light, or the upper part of the side-light if it be more than eight feet high. No brilliant work can ever be produced in a room where the light is allowed to enter from every point of the compass.

As far as side reflectors are concerned, I do not approve of their use except in cases where the subject's face is badly browned from the effects of the sun, or in case of very dark complexions; and even then a little pink powder, judiciously rubbed on the face, will be of greater benefit. But if a reflector is used, care and judgment should be exercised that it is not placed close enough to give rise to cross lights. To those who intend to put in new lights, I would say, step aside from the old method of building large, flat top-lights, and construct one which will do for all kinds of work. Such a light is constructed after this fashion:—Make a large sash, say about 12 by 16 feet, and have the mountings run the short way of the light; now cut an opening in the side of the building large enough to admit this sash. Commence about three and one-half feet from the floor, and allow the sash to incline inward about one foot in three, and have only one large sash, well glazed with double-strength glass. A light constructed after this plan has many advantages over the common flat light, inasmuch as it does not leak, and in northern countries the snow does not lodge on the outside; and last, but not least, the sun never comes far enough north in this latitude to work any mischief with his rays. This sort of light works quickly, giving great brilliancy to the work made under it.

Ground glass is very useful, diffusing the light into all parts of the room, but is at the same time very expensive. Therefore I would recommend all to use a ground glass

substitute on their sky-lights. Flow the side which is to face the room with it, and just try it once, and if you do not like it you can remove it again at a very trifling cost. Tissue paper, which has been brushed over with animal fat (lard), and pressed against the glass, will adhere perfectly, and produces an effect almost equal to ground glass.

All the different parts of an operating room should be painted a very light grey tint; not because it is more beautiful than all other tints or colours, but because any reflection from the wall or any part of the room can be accurately determined as to its actinic force; whereas, if it partook of a chromatic nature, the depth of the shadows on the sitter's face could not be determined with accuracy, and many failures would be the result. But some one will say he cannot afford to change his sky-light and method of working. Very well, then, perhaps your neighbour will see fit to renovate his operating room a little, straighten up his sky-light, and invest in a little tissue paper; for perhaps he is far-sighted enough to see that if he improves his method of working so as to produce more artistic results, the public will appreciate his efforts in their behalf, and be willing to pay an increase in price when they can see an evidence of superiority in the productions from the studio of the progressive artist.

The progressive artist will take advantage of all the little hints and ideas he may see in print, while old Mr. Pinch Nuckle will run along in the old ruts, content with earning a paltry pittance, and eking out a miserable existence. Progressive artists subscribe to and pay for some photographic magazine, from which they glean much of value while Prof. Knowitall will do neither the one nor the other, but instead will occasionally borrow a journal from his neighbour, and invest in patent processes for saving more silver in a month than he uses in a year.

Good, well-lighted, artistic photography will always command good prices, and the photographer who gives attention to the proper lighting of his pictures, and poses his subjects in an easy and graceful manner, will win for himself fame and fortune, while he who ignores all art principles will ere long be numbered with the great mass of those who have tried and failed. All efforts to build up a reputation and to accumulate wealth by lowering prices will be abortive, as fine work and low prices can never harmonize.

SOME FORMULÆ.

The following selection, appearing in our Philadelphia contemporary, were collected by Mr. Gihon from various sources:—

Collodion for Hot Weather.

" Ether	10	ounces
Alcohol	12	"
Bromide of cadmium	1	grain
Bromide of ammonium	1	"
Iodide of cadmium	1½	"
Iodide of ammonium	3	grains

To the ounce of collodion.

"Add to the ether and alcohol, and shake until all is dissolved, filter, and add the cotton. A reasonable amount of age improves this collodion."

Outdoor Photography Collodion.

" Alcohol	1	ounce
Ether	½	"
Iodide of ammonium	2½	grains
Iodide of cadmium	2½	"
Bromide of cadmium	2½	"
Guncotton	5-6	"

"This collodion keeps well, and is good for view and portrait work. If it should become too pale by long keeping, which it will do when the guncotton has been washed in dilute aqua ammonia, tint it with a solution of iodine in alcohol."

Developer.

"Saturated solution of iron...	... 1 ounce
Acetic acid 1 "
Water 12 ounces

"For light drapery or children's pictures use it a little stronger."

Solution for Bath.

"Water 8 ounces
Glycerine (good quality) 4 "
Silver 1 ounce

"Sun it for a few days. Should there be any acid in the silver, put a drop or two of aqua ammonia into it. Then boil it for a few minutes, and give it, after cooling and filtering, a liberal dose of nitric acid. Plates prepared in this bath will allow you to go miles, and come back with a wet plate."

Developer for Outdoor Negatives.

"Glacial acetic acid 1 ounce
Water 16 ounces
Protosulphate of iron 15 to 30 grains

To the ounce of solution.

"The proportions have to be varied so much according to circumstances, that it is impossible to give them exactly. With a little practice one soon learns to regulate the strength of the iron and acid to suit the work in hand. In warm weather the developer can be diluted just before using; consequently, one can carry as much in one bottle as when diluted will make two."

A Good Redeveloper.

"Soft water... 4 ounces
Citric acid 30 grains
Protosulphate of iron 12 "

"To be used with silver solution, twenty grains strong, and applied the same as pyrogallic acid."

Forcing Solution.

"Pyrogallic acid 5 grains
Soft water... 1 ounce
Acetic acid $\frac{3}{4}$ "

"Take enough of this solution to flow the plate, and add three or four drops from the silver bath; flow the plate with this, which will rapidly give all the intensity required."

*A Good Intensifier.**Solution No. 1.*

"Permanganate of potash 5 grains
Water 1 ounce

Solution No. 2.

"Bichromate of potash 10 grains
Water 1 ounce

"These solutions are made up and kept separate, being mixed in equal proportions when wanted."

*Solar Printing.—**Salting Solution for Cartoon Paper.*

"Boiled milk 1 pint
Glacial acetic acid 10 drops
Albumen from two large eggs.	
Bromide of potassium 80 grains
Iodide of potassium 160 "

"Mix thoroughly, and filter. The albumen should be well cut before adding it to the milk. Float or swab the paper with the salting for two minutes.

Sensitizing Solution.

"Water 1 ounce
Nitrate of silver 40 grains

"Swab this on evenly for two minutes.

Developer.

"Water 8 ounces
Pyrogallic acid, 2 heaping teaspoonfuls	
Glacial acetic acid 1 ounce
Bromide of potassium 4 grains

Fixing Solution.

"Water 10 ounces
Hyposulphite of soda 4 "

"Rose-coloured Varnish.—Soak half-an-ounce of red saunders in alcohol, until the colour is extracted; add to any good varnish until the desired shade is obtained.

Ferrotypc Developer.—

"Water 64 ounces
Iron... 1 $\frac{1}{2}$ "
Double sulphate of iron and ammonia 2 "
Acetic acid... 3 "
Liquor ammonia 10 drops
Alcohol 2 ounces
Nitric acid... 16 drops
Sulphate of potash $\frac{1}{2}$ ounce."

Castor Oil in Negative Varnish.—"Varnish made after the following formula will never check nor split on the negative.

"Alcohol 2 quarts
White lac 12 ounces
Gum sandarac 1 $\frac{1}{2}$ "

Castor oil, about one drop to each ounce of varnish."

Cement for Porcelain.—"Soak a quarter of an ounce of isinglass in distilled water until it has swollen; pour off the water, and cover the isinglass with alcohol; the dissolving may be hastened by gentle heat. Next dissolve one-eighth ounce of mastic in three-eighths ounce of alcohol. Mix the two solutions, and add one-eighth ounce of gum ammoniac finely powdered.

"Evaporate the whole in a water bath to the consistency of cabinet-makers' glue. Keep in bottles, and warm for using. Apply to the clean broken edges with a brush, warming the pieces before applying, and keeping the mended dish in a warm place for a time."

MICROSCOPE AND CAMERA.

BY "C. M."

A SIMPLE AND EASY METHOD OF TAKING PHOTOGRAPHS OF MICROSCOPIC OBJECTS.

THE object of writing this is to show by what simple means and ways a photographer with a microscope, and a microscopist with a camera, may obtain very satisfactory results in taking photo-micrographs or enlarged photographs of the "wonders of the microscope."

It seems that existing treatises on the subject, and the apparatus they describe as necessary, rather deter amateurs from trying their hand at this fascinating work. To produce the highest results for histological studies, it is indeed indispensable to have instruments of the highest power and all accessory apparatus for proper illumination; condensers, reflectors, heliostat, &c., together with a thorough knowledge of working the microscope, the extent and complexity of which, most persons can have no idea. This, however, we must leave to the comparatively few select and privileged apostles and ardent disciples of science.

But if we cannot build a palace, we can perhaps build a little cottage, and live in it just as comfortably, though on a smaller scale.

Now then, to business.

The photographer needs—besides what he has and knows—a good microscope that can be inclined horizontally, has a rack-and-pinion arrangement for focussing, and a concave mirror movable in any direction. When you have a microscope, any microscopist will be glad to make you acquainted with its use, if you do not know it already. How to apply it to the camera box afterwards, I shall tell you presently.

* *Practical Photographer.*

The microscopist needs—besides what he has and know^s—a small, half-size camera box, having bellows for extension, a very fine ground-glass for focusing, and a plate-holder perfectly adjusted in focus with the ground-glass^s (this is most important). No photographic lens or objective is required. Any photographer (they are, fortunately, more plenty than microscopists) will make you acquainted with the "dark art," get all the necessary materials, chemicals, and vessels, and arrange a dark closet for you. (How happy the microscopist of the future, when bath and collodion will be things of the past, and dry plates only known!)

Now let us suppose that both the photographer and the microscopist are provided with the working tools and materials as above stated, and have become somewhat expert in their mutual arts.

Get a nice, smooth board about four feet long, and three inches wider than your camera box; fasten cleats or strips of wood along both lengths of the board, for the camera to slide within them firmly but smoothly.

Stand your microscope near one end, and in the middle of the board; incline the tube horizontally, with the eye-piece end towards the camera; push the camera towards it until the microscope enters the round hole at its centre. If much lower than the centre, raise the microscope by an additional piece of board. If much higher, plane off a portion of the board to sink the microscope lower. After the microscope and the camera are thus well centred, fasten the foot of the microscope firmly down by cleats or otherwise. Next, close up the round hole in the camera with thick cloth or felt, leaving or making an opening in the middle, only just large enough to admit the microscope tube, so that no light between can pass into the camera; an additional strip of cloth around the tube may be necessary to shut out every ray of light.

Now, the camera and microscope being well "wedded" together, place the whole board upon a firm table standing close to an open, sunny window, and alongside (not towards) the window, so that the sun can shine on the mirror of the microscope; draw the window shade down so as to shut off the sunlight above the mirror, and a pasteboard or thick sheet of paper may shade the camera, and especially the focussing glass. Everything is now ready to begin work, *secundum artem*.

Beginners will better use a low power objective, and a slide with a coarse object such as a flea or other small insect (transparent, of course) first. Turn on the sunlight by the mirror until a full round circle appears on the ground-glass of the camera. Pushing or sliding the camera towards the microscope enlarges the circle, and withdrawing it makes it smaller; but the eye-piece or tube must of course always be inside the camera. (The eyepiece is *not* taken out for our present work.) Now focus the object as usual by the adjustment screw of the microscope, until a perfectly sharp image appears on the ground-glass. Meanwhile you may have put a plate into the bath, which now will be ready for the plate-holder. Just before taking out the ground-glass from the camera, look once more that the object is fully illuminated. Lose no time now, but place a piece of dark yellow paper between the slide and the objective glass of the microscope to shut off the light; take out the ground-glass and put in the plate-holder, and raise the shield. Do all this with gentle motions. Now lift the yellow paper from the object for three or four seconds only, then replace it again and shut down the shield of the plate-holder. Carry into the dark closet, and develop with a rather weak (say 20-grain) iron developer. You will of course see at once whether the time of exposing in the camera was too long or not long enough, or just right, and govern yourself accordingly at the next trial. In this respect, the photographer has the decided advantage over the microscopist. More time, even ten or fifteen seconds, must be given (owing to feebler lights) when a high power is used, or the camera extended by the bellows to fill up the whole plate instead of keeping the circle of light within it. The greater o

llesser transparency of the object is also a matter for consideration.

The resulting negative may then be used for printing photographs on paper or for making glass positives for the lantern in the usual way. Of course it can be enlarged or reduced to any desired size by copying.

In conclusion, I would say that in the preceding directions I have endeavoured to give in plain language, avoiding as far as possible all technical or scientific terms and phrases, explicit instructions for making photo-micrographs (not micro-photographs) by the simplest means. It is, of course, impossible in an article like this to instruct the photographer in microscopy, and the microscopist in photography; this they must learn of each other. But each will have no difficulty in producing good results after some practical knowledge and experience. I may only remark, in conclusion:—

First: That the morning sun and a cloudless sky is most desirable.

Second: The building, as well as the table or stand, must be absolutely free from vibration during the few seconds of exposure; a waggon passing by in the street shakes the whole building, even when of brick or stone. No walking in the room, of course.

Third: Absolute cleanliness and careful manipulation are indispensable in both branches of the art.

FIRE AT SARONY'S STUDIO.

We learn with regret, from an account in the *York Herald*, that on Monday night week a serious fire broke out at Sarony's photographic studio, at Scarborough, but, fortunately, it was discovered in time to prevent its spreading beyond the room where it originated.

It appears that about midnight Mr. G. Thomas went to the premises for the purpose of attending to the green-house fires, and he then heard the crackling of fire in the building. He at once raised an alarm amongst the inmates, who were all at the other end of the extensive building, and also called P.C. McKenzie, who resides close by, and who has charge of the fire hose stationed on the South Cliff. A messenger was also despatched to the police station, and the Chief Constable gave orders for the reel and hose to be got out and taken to the place. On his arrival, he found that P.C. McKenzie and P.C. Pickering Johnson had, with commendable promptitude, got the South Cliff hose out and attached it to the plug at the end of Albion Road.

In the meantime, the inmates of the house were not idle, and Mr. Tugwell and others were busily engaged in throwing buckets of water on to the fire, which broke out in the ladies' dressing-room on the right hand side of the corridor. Fortunately, there was an excellent supply of water, and a great quantity was poured on the flames, which were eventually subdued and finally extinguished; but not until great damage had been done. It is supposed—though it is not known with any degree of certainty—that the chimney which conveyed the smoke from the engine got on fire, and that this in turn set fire to what is known as a "trimmer."

The whole of the contents of the room are more or less damaged, and many valuable articles are altogether destroyed. The fire having been extinguished, Mr. Fisher, the manager, made a survey of the premises, and in a room immediately over the one in question, and occupied by Mr. Neumans, artist, found that the heat had seriously damaged numerous works of art and several portraits. The large picture gallery, containing many thousand pounds' worth of property, adjoins Mr. Neumans' room, but the contents have fortunately escaped. But for the fact of the fire being discovered when it was, there is little doubt that the structure would have been entirely destroyed. As it is, the damage will be little less than £500, but this amount is, we believe, covered by insurance.

PHOTOGRAPHS RESEMBLING DRAWINGS.

It is somewhat remarkable that whilst several methods are in existence of producing photographs closely resembling monochrome drawings in colour and texture, so few photographers step out of the beaten path, or attempt to produce anything but the stereotyped style of prints on albumenized paper. One of the most charming styles we have seen was that practised by the late Mr. Taylor, of Marseilles, who described his method of printing on drawing paper with borate and phosphate of silver. The prints were of a rich warm brown tint, and were not easily distinguishable from sepia drawings. The subjects selected were landscapes and old architecture, which were most effective in this style. We subjoin the details, and strongly commend the process to photographers wishful to produce work out of the ordinary photographic routine:—

"The materials to be used for the coating solutions are: bleached shellac, borax, and ordinary phosphate of soda.

Solution with Borax.

Water	100 parts by weight
Borax	4 " "
Shellac	8 " "

Solution with Phosphate of Soda.

Water	100 parts by weight
Phosphate of soda	4 " "
Shellac	5 " "

"To prepare either of these solutions, the proper quantity of finely pulverised shellac is put into a bottle, shaken with water, to wash out the soluble salts which may remain from the bleaching process, and thrown on a filter to drain.

"The water, contained in a suitable vessel (*e.g.*, an enamelled iron pot), is placed on the fire, the borax or phosphate dissolved in it, and the shellac added in a damp state. Care must be taken that the water is not too hot when the shellac is put in, or this last will stick together in lumps, which will dissolve with great difficulty. The liquid must be kept gently boiling for about two hours, stirring from time to time. More water must be added to replace that wasted by evaporation.

"As the resin is in excess, all will not be dissolved. The insoluble portion remains as a grey, slimy matter, which chokes the filters very rapidly. The liquid obtained must therefore be allowed to settle for about twelve hours, carefully decanted and filtered, first through the sponge, and then through paper.

"These shellac solutions will keep many months, camphor being put in the bottles to prevent mouldiness. They may be used separately or mixed, according to the colour required, or the nature of the negative to be printed. A

mixture of five parts of the borax solution and one of that made with phosphate of soda gives good results with negatives of mean intensity.

Either ordinary photographic paper or drawing-paper may be used. The following remarks apply more especially to Whatman's drawing-paper.

"The paper should be cut one or two inches longer than the prints to be made, and the extra length doubled over towards the side which is to receive the image. It serves as a handle in the subsequent operations. The sheet to be coated should be plunged into the bath endwise, so as to flood it at once, a glass triangle being used to insure this. The right side of the paper—that which is to receive the image—is to be uppermost in the bath, and the glass triangle passed over every part of it slowly and lightly. After an immersion of about a quarter of a minute the paper is to be drawn out and hung up to dry.

"For rendering the paper sensitive a bath containing fifteen per cent. of nitrate of silver has generally been used, but a weaker bath might answer the purpose equally well. This bath should be filtered each time it is used. The sheets may be floated on the nitrate of silver bath from three to five minutes.

"Although, in some cases, it is advantageous to use the paper in this state of preparation, it will generally be best to let it undergo another operation before printing. This consists in plunging the sheet once more, either in the coating bath first used, or in a similar bath diluted with half its bulk of water; the operation is to be conducted exactly in the same way as for the application of the first coating. The paper thus prepared will be found to keep fit for use a long time.

"Prints on paper that has received but one coating of shellac should be thoroughly washed before fixing; those, on the contrary, on paper that has received a second coating, must be fixed without any previous washing.

"Prints on paper prepared with phosphate of soda alone, or with a large proportion of this salt, take a good tone when simply fixed with hyposulphite of soda, 1 part in 4. But when the shellac solution has been prepared with either borax alone, or borax with a small proportion of phosphate of soda, the best tones are obtained by the use of sulphocyanide of ammonium in conjunction with hyposulphite of soda; these salts may either be mixed in the same bath, or the prints passed first through a solution of the sulphocyanide, and the fixing terminated with hyposulphite of soda alone.

"After the washing, which must be very thoroughly and carefully executed, the dried prints may be considered as being finished. In most cases, however—and especially when phosphate of soda has been used—the appearance and permanency of the prints may be enhanced by saturating them with a varnish composed of—

Bleached shellac	30 to 40 grains
Alcohol	1 fluid ounce.

"This should be flooded over the *back* of the print with a brush, so as to penetrate the whole thickness of the paper, and come out on the face, to which, when dry, it should give but a very slight gloss.

FRENCH CORRESPONDENCE.

PHOTOGRAPHY AMIDST SNOW AND ICE—PROGRESS OF THE SCHEME FOR A GENERAL SYNDICATE OF PHOTOGRAPHY—DR. VAN MONCKHOVEN AND THE GELATINO-BROMIDE PROCESS—COLOURED PHOTOGRAPHS OF M. GERMEIL-BONNAUD.

Photography during the Snowstorm at Paris.—I read somewhere lately that a certain lady, issuing invitations for a dinner party, a day or two ago, headed her notes with the joke, "It is particularly requested that the snow may be rigidly excluded as a subject of conversation." The narrator of the story added that the request was strictly

complied with, but that the party was not on that account any the more lively. So it is with me: when I took the pen in my frozen fingers to commence this letter, and put my hand to the icy-cold paper, I resolved conscientiously not to say anything about the snow, for, I thought, every one has heard enough of it already. But how was I to escape the fatal necessity, if only to tell how all photographic operations have been stopped by the fall of the thermometer, and how the societies devoted to our art have been compelled by the severity of the weather to give up their meetings! One must, indeed, be an ardent disciple to turn out of a warm room for the pleasure of attending a meeting of a photographic society, or of listening to a lecture on photography; for all that, however, the meeting of the Photographic Society of France was by no means badly attended, and M. Davanne's lecture at the Sorbonne, in spite of a temperature registering 28° of frost, and notwithstanding the difficulty of getting about, due to the deep snow which covered the streets of Paris, counted an audience of about two hundred persons. No one was more surprised at this result than M. Davanne himself. In a letter addressed to me on the morning of the same day, he expressed his opinion that he would be compelled to deliver his lecture to an audience of three (not counting the lecture attendant and the hall porter), and those three would be the gentlemen who had kindly offered to assist him with his experiments. If so large a number of persons can be found on such an evening to brave the inclemency of the weather, it is fair to conclude that not only M. Davanne's lectures are always interesting and instructive, but also that they have been found to be of value to those who practise photography as a profession. The fact is certainly worthy of being recorded at a time when the greater number of our theatres have had the option of closing their doors or of playing to empty benches.

The Project for a General Photographic Syndicate.—The only other society which attempted to hold a regular meeting at the usual time and place was the *Chambre Syndicale de la Photographie*, and even that was necessarily adjourned in consequence of the agenda paper containing several subjects of importance, which could only be discussed at a more numerously attended meeting. One of these subjects, as I have already explained in my previous correspondence, is the scheme for uniting all the photographers of France, and perhaps also some foreign correspondents, in a general guild or syndicate for the promotion of photography. Such a project as this, if it be successful, cannot fail to elevate the rank of photography among the industrial arts, and to draw closer the bonds of good fellowship which ought to unite all the members of the profession, as well as to promote the adoption of means for protecting their interests when necessary. The results obtained will be valuable in proportion to the number of those who are interested in the scheme, and who will lend their moral support and the aid of their personal exertions in favour of the common work. My own wish would be to see associations of the same kind formed in other countries, and that by the interchange of mutual relations one general and really international photographic union should be established. So soon as our own syndicate in France is in full working order we shall seek to enter into communication with the more energetic among our foreign brethren, and to induce them to do for themselves what we have succeeded in doing here. From the combination of these efforts we must be able to produce results that cannot fail of being of advantage to the present as well as to the future of the photographic art and industry. It will be seen, therefore, that the Arctic severity of the weather has not rendered us here less fervent in our aspirations for the common weal; on the contrary, we profit by the cessation of work which the great cold renders compulsory, to engage with ardour in schemes that may benefit the interests of the whole photographic body.

Van Monckhoven's Gelatino-Bromide Process.—To return, however, to the cold! There has just arrived an icy communication from the manufactory of gelatino-bromide plates: "Everything is frozen; work quite impossible." There can be no doubt of the truth of this eloquent though laconic report, since it proceeds from our friend Van Monckhoven, who is as indefatigable and untiring in his work as he is ardent and eager in spirit. *Apropos* of the gelatino-bromide of silver, I must not forget to describe the publication of a new work on the process by Dr. Van Monckhoven; it contains "Practical Instructions" which are so precise and clear that it will doubtless have the effect of still further popularizing the process. Nevertheless, my own conviction remains unshaken, that there will always be a difficulty in inducing photographers to make their own plates. Rather the manufacture on an industrial scale of the emulsion plates as it at present exists in England, at Paris, Ghent, &c., will receive an enormous development. It will be improved, and will soon arrive at such a degree of perfection, that all the world of professional and amateur photographers will always prefer getting their plates from some special establishment of the kind, than try to make them for themselves. The preparation of gelatino-bromide emulsion plates is always an exceedingly delicate, if not a difficult operation, and is often exposed to the danger of failure from climatic and other causes. There is reason to hope that at no distant date tourist photographers will be able to supply themselves with sensitive pellicles like those which M. Ferrier exhibited at the late meeting of the Photographic Society of France. The weight of a large quantity of such pellicles is exceedingly small, and their use must tend to develop very largely the application of photography. We have thus a manifest want supplied, and it should not be lost sight of, for, industrially speaking, it promises to be a source of great profit. The idea, indeed, is not a new one; Mr. Warnerke has already for some time introduced to notice, and has on sale, large quantities of his sensitive tissue. This is really a film of iodised collodion made to adhere to a sheet of paper by means of caoutchouc varnish; it is easily detached from the paper by applying benzine to the back of the paper, and this, working through the pores, dissolves the caoutchouc. Ingenious and practical as this process is, I should prefer to have a pellicle ready for development without the necessity of drawing it off a provisional support. For this reason, I desire to draw attention to the gelatino pellicles which M. Ferrier showed me; they are like thin pieces of glass, and have the same transparency as glass, without being liable to break, and the manipulation of them is very simple and plain. Mr. Warnerke might perhaps—if, indeed, he has not done so already—alter the process which he first brought out to one more like that which I have just described. To obviate the difficulty of getting a surface which shall be quite plane and smooth, the sensitive pellicle might be enclosed between two plates of glass, provided that the change be effected in a place where no light can penetrate.

M. Germeil-Bonnaud's Coloured Photographs.—On account of the severity of the weather I was not present at the last meeting of the Photographic Society, when M. Germeil-Bonnaud's coloured photographs were exhibited. I can, therefore, only speak of them by hearsay. I have read descriptions of the process, but, ingenious as it is, it does not appear to me to fulfil all the requirements, either as regards the colouring, or as regards the permanence of the colour; in fact, it takes us back again to all the inconveniences attending printing in silver chloride and fixing with hyposulphite. For this reason a process of this kind can never obtain my sympathy; for, instead of advancing, it is a step backward. Personally I am always longing for the proscription of all current methods of photographic printing which do not render the pictures in absolutely stable colour. It is not my intention to criticise the process of

M. Germeuil-Bonnaud. Up to a certain point it is very good, and it is capable of rendering good service; but, I repeat, it must be received with a certain reservation; and it deserves only a provisional credit, just as the results it produces are provisional. I am very unwilling to say anything which may wound the feelings of an estimable colleague, but I cannot change my views in favour of unstable processes. They are no doubt still capable of doing good service, and I am quite willing to recognize what they have already done for us. I am, therefore, far from despising them. But I am always sorry to see, among the novelties which are continually being introduced, some which are produced by methods that ought, as I think, to be more and more discontinued. With these views I cannot but regret that the process of M. Germeuil-Bonnaud, excellent as it is in my idea, should require manipulations which are now only counted among the tolerated details of our art, not among the signs of progress.

LEON VIDAL.

HEATING A TONING BATH.

BY S. L. PLATT.*

WE all know how perplexing it is when one is toning to have to stop and get two bricks to place under a toning bath to raise it so we can use an alcohol lamp. Usually one end is higher than the other, so the solution runs all to one end; then the lamp heats all in one spot. I have a tin stand three

inches high, just the size of the bottom of the toning dish. The top piece is one-quarter of an inch from the bottom piece, which forms a hot-air chamber. The bottom piece has a large hole in it, covered with a loose piece of tin.

The lamp flame strikes the loose piece and fills the chamber with hot air, which warms the whole top evenly.

This also makes a fine thing to dry plates on.

COPYING PAINTINGS.

OUR Philadelphia contemporary gives an interesting description of the studio and arrangements for copying employed by Messrs. Overbeck in Dusseldorf. It says:—

“The first great object is to light the subject properly. The copying room of the Messrs. Overbeck is very large, and perhaps eighteen feet high, with high front and side-lights. All the walls and objects in the room that would act as reflecting surfaces are carefully blackened, and all extraneous light is shut off from the lenses by long cones, which reach out as far beyond the brass work as possible.

* Philadelphia Photographer.

The camera is placed on wheels, which run on an iron track nearly the whole length of the copying room, and fastenings supplied to make it rigid in any desired place. The painting is placed on an adjustable stand, and is coated with thin linseed oil previous to copying, in order to clear up the shadows, &c. A Steinheil lens is used, and is declared by the Messrs. Overbeck to be the best for flat surfaces. The exposure varies according to the intensity of the light. In the chemical manipulation of the negative, we saw no novelty except in one instance. Many of the copies are very large, and in making such it is very difficult to get a uniform thickness of collodion all over the plate. Messrs. Overbeck first coat the plate in the usual way, and then turning it end for end, re-coat it, and thus have quite the same thickness of film all over the plate. This double coating of collodion also tends to keep the plate moist, which is a very essential thing in making the long exposure necessary when copying an oil painting. Plates thus treated will bear exposure at least two hours—a hint for those who have interiors, &c., to make.”

SOLAR ENLARGEMENTS BY DEVELOPMENT.

TAKE sixteen ounces of fresh milk; skim off any cream that may be on it, then boil it; next add one-half an ounce of acetic acid; then shake and filter until it is perfectly clean. Next add three grains of iodide of potassium, and two of bromide of potassium to each ounce of the above filtered milk solution. Put this on your paper the same as you would swab on any solution, with a tuft of clean cotton, and then let it dry. When you have your focus taken, and ready to expose, take one of your sheets that is prepared as above, and tack it on your printing-board, and swab or brush on the same way as above a solution of nitrate of silver, thirty grains to the ounce of water, making it slightly acid with acetic acid. Then place it while wet in the position that you had focussed to, and expose it until the print shows in the shadows not very strong. It is then done. Take off and swab on again a solution of eight ounces of water, fifteen grains of pyrogalllic acid, and one ounce of acetic acid. This must be done very quickly and smoothly. The picture will appear instantly, and as soon as you think it dark enough, place it in your hyposulphate bath. An old hypo bath is better than a new one; one that has not been used too much. The time of printing takes generally, when the negative is just right, from one to two minutes. Care should be taken to keep all diffused light from striking the paper.—*Practical Photographer.*

A PHOTOGRAPHIC ACTION.

At the Metropolitan County Court of Bloomsbury the case of Pheimister v. Stanton was heard before the presiding judge, the plaintiff, being a photographer in Camden Town, suing the defendant, an actress, to recover the sum of £2 for certain cartes-de-visite ordered by the defendant, and delivered to her address in the Arlington Road. The plaintiff, being called, proved the order being given, the proofs being delivered, of the account having been applied for, and payment refused. His case terminated, the defendant, called, said she told the plaintiff that she required the cartes at once, as she had to send one to a provincial manager with a view to an engagement, which she had lost in consequence of the photographs not arriving in time. She at once sent them back, but as the plaintiff re-delivered them to her, she refused to pay for them, as they were utterly useless to her now, having got others in their place. The plaintiff, being recalled, denied there was any specific time mentioned, but that he was to do them as soon as possible. At this stage of the case his Honour was of opinion that the plaintiff was fully entitled to recover the whole amount claimed, but at the same time the defendant was entitled to have her photographs.

Correspondence.

A WARNING TO OXYGEN MAKERS.

DEAR SIR,—A few days since, a gentleman at Weymouth wrote to a London firm stating that, having filled a retort with oxygen mixture, an explosion occurred when it was placed on the fire. Enclosed in the letter was a sample of a black powder which he had used as peroxide of manganese. Upon examination, I found it to be sulphide of antimony, a substance that, when added to chlorate of potash, forms a highly explosive mixture very similar to gunpowder.

As fatal accidents are on record resulting from similar mistakes, I would earnestly recommend every amateur oxygen maker to test his chemicals before using them, for there are several equally dangerous "black powders" which an ignorant or careless dealer may supply as peroxide of manganese. A simple test is to pound a little of the mixture and apply a light; if it refuse to burn it may be safely used, otherwise the danger is obvious.—Yours faithfully,

R. PEARSON.

INTENSIFYING GELATINE NEGATIVES.

DEAR SIR,—I note that your correspondent, Mr. A. J. Jarman, has adopted (and modestly described as his own) my method of intensifying gelatine plates with mercury and hypo. The formula given by your correspondent in last week's NEWS is, however, anything but correct. I therefore give for the benefit of your readers the formula which up to the present time I have found most efficient:—

Bichloride of mercury (dissolved in 6 ounces of water)...	...	60 grains
Iodide of potassium	90 "
Water	2 ounces
Hyposulphite of soda	120 grains
Water	2 ounces

Pour the iodide solution into the mercury solution, then add the hypo, when the red precipitate caused by the addition of the iodide will be immediately re-dissolved, and the solution will be ready for use. The above mixture may be used in a dipping bath or dish, or poured over the negative after fixing. The intensifier, made as above, acts very quickly, a few seconds being usually sufficient to give printing density to the thinnest negative; if required to work slower, add more hypo, which will also alter and improve the colour of the negative, and prevent any tendency it may have to become of a yellow or orange tint in the half-tones. Wash well after intensifying.

The above method is acknowledged to be at present the only really practicable method of intensifying gelatine negatives. Trusting it may prove of service to your readers, I am, dear sir, yours very truly,

B. J. EDWARDS.

6, The Grove, Hackney, London.

A SUGGESTION.

SIR,—I am not aware that the idea which I propose to throw out to your readers has ever been executed.

It is this, and I think it would be greatly appreciated by the travelling public: to produce a photographic copy of a first-class map of England and Wales of such a size as to be clearly legible, and at the same time convenient for carrying in a purse or pocket-book. In addition to the map, with a little trouble, could be added, in writing, tables giving the names of the different towns in alphabetical order, their populations in 1871, the railway fare from each, and the number of miles by road to London. To these tables, so as to give the map a special value to each different trade, might be added one giving the short name and address of tradesmen in a special line of business, as, for instance, "The Printer and Bookbinder's Map of England and

Wales" would contain the names of printers and bookbinders in this style:—Aberdare; Brown, High Street Jones, Broad Street.—Banbury; Robinson, Oxford Street; and so on. These names can all be found in Kelly's Directories of the various trades of the Kingdom. At the present time, when there are thousands of working men moving from one place to another in search of employment, an article of this kind—if it could be produced at (say) one shilling or less—would doubtless find a ready sale.—I am, yours, &c.,

ONE WHO WALKED RECENTLY OVER
1,000 MILES IN SEARCH OF WORK.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE usual monthly meeting of the Photographic Society of Great Britain was held at the rooms of the Society, Pall Mall East, JAMES GLAISHER, Esq., in the chair.

The minutes of the last meeting having been read and confirmed, Messrs. William Huggins, D.C.L., F.R.S., &c., H. Manfield, W. Wheeler, and Charles Sands were elected members.

Herr WARNERKE resumed his paper on "Photometers," the first portion of which was read at the last meeting of the Society. At the conclusion of the reading of the paper, Herr Warnerke exhibited his photometric apparatus, the measurements of which were determined by the use of ferric oxalate, and stated that on another occasion he should be pleased to continue his observations on photometers, as he had not that evening spoken of those photometers based upon the combination of chlorine with hydrogen, and especially upon one recently introduced by himself based upon phosphorescence. The paper will appear in our pages in a future issue.

CAPTAIN ABNEY observed that the paper just read was of considerable interest to him, as he had made photometry an especial study. Herr Warnerke's own photometer was undoubtedly a valuable one, and he (Captain Abney) had had an opportunity of seeing it at work in Herr Warnerke's laboratory two or three years ago. He had himself made a rough copy of it, and found it to answer extremely well. There were, however, one or two things in the paper upon which he should like some information. In the first place, what was the sensitive liquid used by Herr Warnerke?

Herr WARNERKE explained that it was ferric oxalate.

Captain ABNEY remarked that transparent photometers, such as that used with ferric oxalate, had other sources of inaccuracy besides those arising from changes of temperature, barometric pressure, or the sudden divergence from light to darkness. Ferric oxalate absorbed light in different proportions according to the thickness of the colour of liquid, and consequently it was never possible to utilize the whole of the so-called actinism of light. On some days the yellow rays were more active than the blue, while on a summer's day he had found three hundred times as much blue as on an ordinary day in winter, when the yellow ray was more intense. Roscoe's photometer, which he (Captain Abney) had used for some years, and in which chloride of silver paper was used, was not an accurate instrument; but it was a close approach to accuracy. The only accurate photometer, he thought, would be one which was capable of receiving an exact impression of the whole of the spectrum. He had made several photographs of the spectrum, showing the difference between the light in summer and in winter. Herr Warnerke's photometer would answer admirably to time the exposure of negatives, but was scarcely fit for exact scientific purposes. He (Captain Abney) had constructed a photometer, however, which he should have pleasure in bringing before the Society, and by means of which it was possible to photograph the spectrum during every quarter of an hour of light.

Herr WARNERKE said that what Captain Abney had stated about the difference of absorbing powers was perfectly true. At some future time he should have some observations to offer on this subject, taken not only from his own experience, but from the experience of others. He might remark, in regard to his own photometer that the difference, in absorption was not of much consequence so far as the asphalt process was concerned, because asphalt was more affected by the red rays than by any other.

Captain ABNEY remarked that Dr. Monckhoven's photometer, referred to by Herr Warnerke, was identical with a process used by Niepce de St. Victor forty years ago.

Herr WARNERKE observed that this was the case.

The PRESIDENT, having referred to the value of the paper read by Herr Warnerke, enquired whether that gentleman would at the next meeting bring the new photometer to which he had made reference, and also made a similar inquiry of Captain Abney.

Herr WARNERKE and Capt. ABNEY both replied in the affirmative, and a unanimous vote of thanks was then passed to the former or his paper.

The PRESIDENT then stated that in pursuance of a resolution passed in February 1878, when the Society offered two prizes of the value of £5 and £2 respectively to be given to the successful competitors in an examination in skilled photography in connection with the Society of Arts, a communication had been made to that Society to this effect. A letter had, however, been received from the secretary stating that though the council had accepted the offer, no competitors had presented themselves, and consequently they had handed over the prizes to the City and Guilds of London Institute.

Captain ABNEY then moved, and Mr. Sebastian DAVIS seconded, that this action be approved.

A paper by Captain Abney was then taken as read, and the meeting adjourned to the 13th January, 1880.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

Rules of the Monthly Artistic Competition in Photography.

1. That the competition be monthly, and pictures intended for competition must be sent in before the day of meeting, addressed to the Hon. Soc., Society of Arts, Adelphi.
2. That at each meeting the President shall announce a name or title for the subject of the picture to be exhibited at the next meeting.
3. That the first subject be announced at the January meeting, 1880.
4. That the size of the pictures, landscape or figure, be 12 by 16 or under.
5. That a private mark *only* be attached to each picture, but an envelope bearing similar mark outside, and containing proper name and address, be delivered with each picture, such envelope to remain unopened until after the awards.
6. That two artists, not photographers, be appointed by the committee to judge the pictures.
7. That medals or other prizes be awarded at the end of the year.
8. That the exhibits become the property of the Society.

BERLIN ASSOCIATION FOR THE PROMOTION OF PHOTOGRAPHY.

The first meeting after the recess was held on the 19th September, Professor H. W. VOGEL in the chair.

Herr E. RISSE, of Dortmund, sent some specimens of a new process called, by the inventor, *Albatype*. A thin iron plate is coated with plain collodion in which is suspended finely powdered heavy spar (barium sulphate), thus producing a chalky-looking surface. In preparing such a surface, collodion is preferable to gelatine, on account of its drying quicker. Over this surface is flowed a film of silver chloride, on which the object is taken, and the plate is then treated in the ordinary way. The image is dull, but well modelled, and resembles a carbon print on opal glass.

Herr REICHARD mentioned that Herr Talbot had formerly suggested similar plates for carbon printing, and had himself worked with such, but he had prepared them with gelatino and heavy spar.

The PRESIDENT laid before the meeting some instantaneous photographs taken by Obernetter with his own emulsion. These pictures excited universal admiration. Dr. Vogel also gave some particulars of Obernetter's latest experiences with the emulsion process.

Herr SCHULZ took the opportunity of stating that he had kept a sample of Obernetter's first emulsion from February to July, and found it at the end of that time in perfect working order.

Mr. WIGHT had kept the same emulsion to the middle of August with complete success, but found it necessary to keep it in an ice-safe during very hot weather.

The PRESIDENT exhibited to the meeting some first proofs of a peculiar photographic process by Herr Falk. These were reproductions of an oil painting. The negative is first copied on to a steel plate coated with sensitive asphalt, and the latter then etched. One of the peculiarities of the process is, that in consequence of the treatment of the asphalt, a visible grain is formed in the asphalt itself. He also showed a couple of paper covers for pamphlets, both which, having been exposed in front of a window during a summer month, had been bleached by the action of the light in a very remarkable way. The speaker took occasion to point out the existence of a mistaken, though generally received opinion, that aniline colours are more permanent than others. Even the yellow silk stuff dyed with picric acid—the so-called oiled silk of the Parisians—which is so much used for tent windows, faded very soon.

Mr. WIGHT could recommend strongly a yellow calico manufactured by a house on the Rhine; he had found it to keep its colour unchanged for fifteen years.

Herr SCHAARWACHER exhibited some pictures taken by the patent process of M. Germeul-Bonnaud. The process consists in slightly copying a picture on paper with a dull surface, and then colouring it with smooth colours specially prepared to be able to withstand the subsequent operations. The paper is then coated with salted albumen, silvered, fully copied under the same negative, and finished in the usual way. The speaker showed specimens of prints in both stages of preparation. The appearance of the finished pictures is a very striking one, but it was thought generally by the members present that the same effect might be obtained by skillfully painting ordinary prints, thus dispensing with the second operation of the process. According to the inventor, this second operation protects the colours, and makes them more permanent, but doubts were expressed on this point.

The gelatine negatives taken by Mr. Wight during his late tour were received by the meeting with signs of great interest. They were taken on gelatine plates prepared by himself in April last; these were exposed during the summer months, and have been only recently developed. As objective he used Ross' rectilinear lens, which he found to work with ease, and to give correct drawing with a large angle.

Dr. VOGEL thought that Stenheil's achromatic landscape lens would render the same service, and be cheaper.

Mr. WIGHT remarked, besides, that the determination of the proper length of exposure had caused him very great difficulty, though a correct result depended materially on it. He described also a visit that he had made to the establishment where Messrs. Wratten and Wainwright, of London, manufacture their gelatine plates. Notwithstanding the great extension of this establishment, and the fact that eight men are occupied solely with coating the plates, consumers are so numerous that they have often to wait weeks before they can get their orders completed.

PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.

A MEETING was held on October 7th, the President, H. J. NEWTON, in the chair. Minutes of last meeting read by Secretary, and approved.

Mr. TAYLOR exhibited to the Section an actinometer primarily constructed to facilitate carbon printing, the invention of Mr. H. J. Burton, of London. Exhibiting the instrument, he said the invention was based upon the well-known resistance offered to the transmission of light by a numerically progressive series of coloured media, the opacity of which increases in a definite ratio with each increase in the order of the numerals. It consisted, as they would see, of a small box the lid of which was capable of sliding backwards and forwards to a limited extent. Making use of language he had adopted elsewhere when originally describing the actinometer, he would say that "the cover was glazed, half being deep orange; the other half is clear glass, on it being printed the numerals up to 10. The first of these is so feeble as to be barely visible; the second is more dense, and so on up to the last, which appears by contrast with the first to be entirely opaque, although on minute examination it is found not to be so. On a convenient portion of each figure is impressed a solid but minute black dot, the object of which will be presently explained. The actinometer contains a small roll of sensitive paper, so prepared as to retain its purity for months. This band may be drawn forward over a flat and firm cushion, and by means of springs presses firmly against the numbered half of the glass plate. On exposure to light for even a few seconds the paper

darkens sensibly, but the precise degree cannot be perceived by looking upon the surface. In order to ascertain the intensity of the luminous action, the cover of the actinometer is slid forward, by which the orange glass is made to cover the paper that was exposed, and upon which may now be seen the whole of the figures, which are white upon a ground more or less darkened according to exposure. But something more than the figures will be seen. I have said that there is an opaque dot upon each figure, and that dot will be seen in the print upon each numeral precisely in relation to the exposure given. With an exposure of a few seconds the dot on fig. 1 will be plainly visible; a little longer shows that on 2 and so forth, each figure in the ascent being more opaque than the preceding one, and resisting longer the transmission of the light. But the capability of registration is not limited to the "resolving" of the indicating dot up to the last figure of the scale; for as the exposure proceeds and brings into view the dots on the higher numerals it is all the time penetrating through the lower ones and merging each figure progressively into the background. Hence by this secondary registration the range of the actinometer is greatly increased. He then described the manner in which the albumenized sensitive paper was prepared so as to retain its sensitiveness and purity of colour for a few months.

Mr. MASON: Is this paper as sensitive as our ordinary albumen paper?

Mr. TAYLOR: You can make it as sensitive as you choose by adding gallic acid to the ordinary bath.

Dr. MILLAR said that the addition of orange glass is a very valuable one to the old actinometer, that has been used so long, especially in carbon printing.

Dr. VANDERWEYDE: I would suggest something about actinometers. It has to be experimented upon. In the first place, it has to be placed screened from the back of the camera in a kind of hood or funnel, so as only to be affected by the light coming from the object to be photographed; if exposed to other light than that it cannot be a true criterion of the intensity of light which falls on the camera. Secondly: Every actinometer must be used under the same conditions of exposure as the plate itself. I would suggest experiments with the radiometer. I have one of Prof. Crookes' in my room to measure the electric light. The standard candle is an absurd measurement. The radiometer in clear bright sunlight at midday makes 100 revolutions per minute; at 7 o'clock in the morning it shows a tendency to revolve; at 9 o'clock it revolves pretty rapidly. If I place it at such a distance from the electric light, and count the number of revolutions it makes, then I have my data—my electric light in comparison with sunlight, if you want to express it—so many feet from the electric light, so many thousand miles from the sun. If you place such an instrument on the top of the camera, and screen it from the light from behind with a hood blackened inside, and so constructed that the opening for the light which falls upon it is the same field that you are taking a picture of, and count the revolutions, then you would only have to wait until that instrument makes the proper number of revolutions in a given time before you take your picture. The other more doubtful question is heat. Caloric rays are of no use to photographers, and the question is how far the caloric rays act upon the instrument. I have made experiments upon the radiometer; I tried it with different coloured glass, and found that red rays retard it more than violet rays. If it is only affected by heat, as some few assert, it is of no use for photographers; but I deny that. However, I wish to remark this, that the instrument I have is so sensitive that if you put your warm hand on it it will revolve, but in an opposite direction.

Mr. NEWTON: I have one or two negatives to exhibit. I made some experiments with the new developer first introduced by Mr. Henderson. His process, or the modification of it by Mr. Fry, was to make a saturated solution of ferrocyanide of potash and pyrogallic acid. He reduced it about one-half with water and added two grains of pyrogallic acid, for a stock solution. When he wished to develop, he took sufficient of that to flow his plate, and added a few drops of ammonia, and he claimed to have obtained very excellent results, reducing the time one-third. In my experiments I discarded the ammonia, and instead of making my stock solution with the pyro., I made it with the carbonate of soda solution added to the yellow prussiate. The reason why I reject ammonia in the developer, is because the ammonia is a very unstable chemical compound, whereas the carbonate of soda is a very permanent salt, especially after it has parted with its water of crystallization. The solutions I prepare by dissolving one ounce of ferro-cyanide in six

ounces of water, to which is added twenty grains to the ounce of carbonate of soda. When about to use I take sufficient to flow the plate, and add two or three grains of pyrogallic acid. I found, when using it on a newly prepared emulsion, a very little bromide of ammonium was necessary; but with an emulsion a month or two old, no bromide is required. I have made some fine instantaneous negatives with the developer, using emulsion about two years old. I have procured the ferro-cyanide from four different dealers, to determine whether the ordinary article in the market was, as a rule, reliable, and would give uniform results. So far, I have discovered no difference in the behaviour of the several samples obtained. I have not experimented sufficiently with dry plates to speak definitely, or not as positively as Mr. Fry, on this part of the subject. If, however, I was to advise at this present time, I should recommend the use of a small quantity of bromide when using it for developing dry plates.

Mr. WILLIS developed several prints by his platinum printing process, and read the following remarks on the subject:—"Two years ago I had the pleasure of introducing to you my first process for printing in platinum. This process necessitated the employment of silver, a gold toning bath, and hyposulphite of soda. It was found that unless the prepared paper had a preliminary coating of silver, the particles of metallic platinum reduced during development would not adhere well to the surface, but would partially float away. The image given by this process consisted of platinum with a trace of gold; but unless very carefully worked there was a tendency to produce prints containing silver also. Moreover, a sulpho-cyanide toning bath frequently gave yellowish whites, due to the formation of sulpho-cyanide of iron. The use of silver and hypo in the process was a blot which I was anxious to remove. After some experimenting I discovered that by adding a salt of platinum or iridium to the oxalate of potash developer, the use of silver could be dispensed with. In my new printing process, neither silver, gold, nor hypo is used. I will now proceed to illustrate the method of working. The sensitizer is made by mixing equal quantities of the following solutions:—1st. A solution of ferric oxalate; 2nd. A solution of potassic chloro-platinite. This mixture is spread on the paper by means of a pad of cotton-wool, or, better, by a piece of flannel wound around a soft rubber tube. As soon as the coated paper has become surface dry, the drying is completed before a fire or stove or in a hot cupboard. It is now ready for exposure. The exposure is made under a negative in the ordinary manner, the proper duration of exposure being determined by inspection; all details should be visible.

I may here remark that the sensitized paper may be kept in a calcium tube without any deterioration for at least six months.

The developer is made by mixing a solution of oxalate of potash with a solution of the platinum salt before mentioned. This mixture is now heated to nearly the boiling point, and the exposed prints are developed by floating them upon it for one or two seconds. After development the prints are simply washed in a weak solution of citric acid and then in water. The object of this washing is to remove the iron salt from the paper. The advantages by this process may be thus briefly enumerated: 1st. Absolute permanency of the prints. The image consists of metallic platinum only, and is untouched by any chemical agent save only warm *aqua regia*. 2nd. Its extreme simplicity, obvious to all. 3rd. Great certainty. Very little chance of failure even in inexperienced hands. 4th. Easy applicability to various surfaces, such as linen, cotton, satin, and ceramic wares.

Dr. VANDERWEYDE asked for the chemical reactions involved in this process.

Mr. WILLIS: This process is based on the following chemical reactions: 1st. A solution of ferrous-oxalate in protassic-oxalate instantly reduces the metal from salts of platinum. This reaction was discovered by me some years ago. 2nd. Ferric-oxalate under the action of light is reduced to ferrous-oxalate. This fact was well known very early in the history of photography. To explain how these reactions are made use of in the process I will call your attention to the composition of the sensitive coating applied to the paper. You will remember it was composed of a mixture of ferric oxalate and of a salt of platinum. Now if this paper be exposed to the action of light the ferric-oxalate will be reduced to ferrous-oxalate, but the platinum salt so intimately mixed with it will remain unaltered, so that, after such exposure to light, the paper will have a coating of ferrous-oxalate and platinum salt in place of the original coating of ferric-oxalate and the same salt. Now if we float or immerse this coated paper on which light has acted in a solution of potassic-oxalate the ferrous-oxalate

will be dissolved from the surface of the paper, but at the moment of its solution the ferrous oxalate will reduce *in situ* the metal from the salt of platinum with which it is so intimately mixed. It is easy to understand that if the coated paper be exposed to light under a negative, the ferrous-oxalate formed in those parts on which the light has acted will, when floated upon the potassic-oxalate solution, reduce the platinum salt in contact with it and leave a picture in metallic platinum.

Mr. MASON: In working this process, supposing you employ a printer and give him a certain number of negatives, could he make those prints as readily as he could make albumen prints, provided he is accustomed to working the process? Would he make them faster or as fast?

Mr. WILLIS: He would make them faster. The exposure is about one-third of the time required by silver printing. The meeting then adjourned.

Talk in the Studio.

ENGLISH MOUNT AND MANUFACTORY COMPANY (LIMITED).—The attention of photographers has recently been called by advertisement to a new company for the production of mounts, cards, &c. We notice from the report of the company that its prospects, as a company, are exceedingly promising, the accounts showing something like 15 per cent. on share capital, as well as the prospect of general success. Such a prospect is in every way satisfactory, as illustrative of the satisfactory conduct of the business of the company. Our readers will see in our business pages some details of this prospect of success, to which we now draw their attention, and shall further refer to the subject as information comes under our attention.

FIRE.—We regret to learn that a serious fire in Philadelphia has destroyed the premises and much stock of Messrs. Collins and Co., the chief house for the supply of cards and mounts to American photographers.

IMPROVEMENT IN SILVERING GLASS.—The plan of coating mirrors with a thin film of silver, though superior to the old amalgamation process, has some drawbacks. The ordinary treatment is as follows: The glass is laid on a horizontal table of cast iron covered with a woollen cloth and heated to 40° Centig. (104 deg. Fah.) On the glass, previously well cleaned, are poured successively a solution of tartaric acid, and then another of ammoniacal nitrate of silver. Under the influence of the heat the organic acid reduces the metallic salt, and after about twenty minutes the silver is deposited on the glass in adherent layers; the whole operation does not occupy more than an hour. The mirror is then dried, and the metal covered with a varnish sufficient to protect it from friction and the action of sulphur vapours, which blacken it. But silver deposited in this way often has an unpleasant yellowish reflection. M. Lenoir, of Paris, turned his attention to discovering a process which would obviate this drawback. He has succeeded by the following means. The glass, once silvered, is subjected to the action of a dilute solution of the double cyanide of mercury and potassium, when an amalgam of white and brilliant silver is formed, adhering strongly to the glass. To facilitate the operation and utilize all the silver employed, M. Lenoir, by a recent improvement, sprinkles the glass at the moment the mercurial solution is applied with a very fine powder of zinc, which precipitates the mercury and regulates the amalgamation. Mirrors thus treated no longer give, it is said, the yellowish images of the silver used alone, but the white and brilliant reflection of the old process, without the emanation of vapours which would be injurious to the men employed upon the operation.

To Correspondents.

THE YEAR-BOOK OF PHOTOGRAPHY, 1880. In order to facilitate our labours in preparing the YEAR-BOOK OF PHOTOGRAPHY for next year, we shall be greatly obliged to those of our readers who can favour us with brief practical papers on subjects arising in their experience, so that our annual may be, as it is designed, a complete record of the progress of the year, and a trustworthy practical guide for the future. As the time approaches at which we must go to press, we shall be greatly obliged if copy can be sent without delay.

PERSEVERANCE.—Probably various causes have contributed to your failure. No. 1 is over-exposed, beyond a question. No. 2 is also over-exposed, but it is nearer the mark. No. 2 may, we think, be improved by intensifying; possibly No. 1 may also. Try, for intensifying, the preparation described by Mr. Edwards on another page. Mr. Edwards' intensifier is a modification of the iodide of mercury intensifier, and gives exceedingly good results. No. 3 seems to be under-exposed. You will note that there is no detail in the foliage; but this seems partly due to imperfect lighting. It is desirable, if possible, to have a direct light on subjects, like foliage, reflecting very little light. It is possible that No. 2 would have been a good negative with more judicious development. In such a case, use a larger proportion of pyrogallie acid, which will give more force and "pluck." It is possible that some of the plates may have been faulty, as you suspect, but it is more probable that the fault was in the treatment of an inexperienced hand.

CAPTAIN TURTON.—You will find the pyro developer better, we think, for collodion prints on opal than iron. A simple form of the developer consists in 2 grains of pyrogallie acid, and 20 minims of acetic acid in an ounce of water. A very good formula consists in 3 grains of pyro in an ounce of water, 1½ grains of citric acid, and 20 minims of acetic acid. 2. So far as we know, our impression of the platinotype process is favourable; but we do not know much. Some of the prints in the Exhibition were very good. The manipulations, so far as we have seen them, seem simple and easy. As to whether cheap or not, we do not know. 3. We have heard of gelatine plates being successfully worked in plenty of orange light; but the attempt is not safe. Better try a developing tray with ruby glass top. 4. The firm in question do manufacture collodion bromide plates as well as gelatine plates. Probably they were sent out as bromide emulsion plates. The enlargements by the firm you name are, we believe, produced by the Autotype Company. We believe the second firm you name trustworthy.

C. B.—You will judge best by trying; that is, placing the tint upon a few different colours. We should suggest maroon as a good colour. It by contrast will give the colour of the prints a warm black effect. If you wish to make the tone of the prints look as warm as possible, then use a greyish green velvet, or a simple grey tint.

W. B. C.—Your letter was received too late last week for a full answer. We recommended you to obtain a work on the magic lantern published by the Stereoscopic Co., or one by Mr. Chadwick, whose address is Princes Bridge Iron Works, Manchester. See his advertisement of an Oxygen Generator in last issue of News. Oxygen is made by mixing intimately four parts of chlorate of potash with one part of powdered black oxide of manganese. The mixture is placed in a retort suited for the purpose, which is placed on a moderate fire. A tube passing from the top of the retort conveys the gas as it is generated into a purifier filled with water, and the gas after purification passes through another tube into the gas bag. The process is one requiring care, and is better not undertaken by an entirely inexperienced person, as it involves some danger.

NEMO.—We scarcely understand the phrase "stopping negatives," but glean from other remarks in your note that you wish to coat some portions so as to retard the printing. This can be done in various ways. A little collodion or varnish tinted by means of an aniline or other non-actinic colour applied at the back of the glass answers well; or a little tissue paper or tracing paper is very efficient.

A. L. E. D.—In our next.

Several correspondents in our next.

THE OPERATING ROOM AND DARK ROOM.

THERE is no part of the photographer's premises of greater importance than the operating room and dark room, and none upon which so little has been said and written. We never remember to have met with a paper or discussion on the subject at a Society meeting; nor have we met with anything written on the subject except an occasional chapter in some of the older manuals. Hence there are no definitely accepted canons of proportion and construction, no plans and arrangement, the result of accumulated experience, collected and compared. As a rule, each photographer makes and arranges his dark room according to his own ideas—or, rather, according to the exigencies of space and facility which his premises present. It is not usually regarded as of vital importance, and hence any corner or cupboard which can be spared is made available for the purpose.

In offering a few remarks on the subject we shall suggest rather than dogmatize; but on one or two points we shall speak imperatively. It is very desirable that more space than is absolutely necessarily usually devoted to the department should be given, and it is that it should be well ventilated. The photographer inevitably spends many hours in the operating room, and the work will be better done, and the health materially benefitted, if the room be airy and well ventilated. In how many establishments is the dark room a small cupboard which chances to be handy, or an inconvenient corner partitioned off from the studio! In how many, also, is it made the receptacle for all kinds of disused apparatus, empty packing cases, cracked dishes, and all kinds of rubbish which gradually accumulates!

We have spoken of the operating room and dark room as distinct places. It is only too common to have a dark room only, in which various of the operations belong to the operating room—such as coating the plates, &c.—are conducted. But connected with every photographic establishment there should be an operating room, a portion of which may be made into a dark room. Before we enter, however, into details of our own conception of a convenient operating room, we will quote the description given by Mr. Lake Price, in his excellent Manual, of what an operating room should be. He says:—

"Small and inconvenient dens may be made to do duty on occasion; but if it be possible to obtain a certain space, say sixteen feet by twelve, for the purpose, it will be well bestowed, both in the increased convenience for the production of the negatives, and for the health of the operator, by the superior ventilation it affords.

"The aspect should, if possible, be N.E., to avoid the direct rays of the sun upon its yellow blinds; the window should be glazed with yellow glass, by the light transmitted through which paper may be excited and bath solution prepared; but in operating for the camera, a curtain of one, two, or three thicknesses of yellow tannin in addition will be found necessary, according to the greater or less sensitiveness of the preparations.

"The room should have a fire-place for warmth in winter, and ventilation, or drying of excited papers; and if there is a small boiler for hot water to the stove, it will be found advantageous in a variety of manipulations.

"A large Arnott's ventilator at the top of the room in the flue, and an air-shaft, diaphragmed, not admitting light, with small flap doors to close when desired, at the level of the floor, near the developing sink, will assist to carry off the fumes of the chemicals.

"Two sinks lined with gutta-percha, with wastepipes of the same material, should be fitted entirely separated from each other; one for developing the picture, the other for standing the negatives in to steep in water, which should be laid on with several taps to both sinks. Gas likewise should be fitted along the sinks with deep yellow glass chimneys to the burners. Shelves for bottles, and a well-made close-fitting cupboard for chemicals, are wanted; at the same time it is especially advised not to make the shelves of the dark room receptacles for all the nameless rubbish apt to accumulate in such a locality, and thereby establish dust-traps, to the certain deterioration or destruction of future pictures.

"Let the dark room only contain those things which legitimately belong to it; let the shelves, &c., be washed frequently and kept free from dust, the sinks in the cleanest condition, and the floor covered with oilcloth, as being the material with the most unbroken surface and most easily purified from dirt.

"It is imperatively necessary that not the slightest gleam of white light be allowed to penetrate into this room whilst operating; plates may be spoiled one after the other by a half-open keyhole opposite them when draining, or by a forgotten cranny at the bottom of a door. Curtains to remedy this are not proper; they accumulate dust in their folds, and the movements on drawing them disperses its motes though the air of the room, to settle ultimately on the film; if the doors are leathered, or have wooden fillets screwed round them, either are quite as effectual in excluding light, and more cleanly.

"Note, that if lead linings or pipes are used for the sinks, they will be acted upon by the chemicals, will soon be full of holes, and the vapours of their combined action are most unwholesome."

We shall return to the subject in a future issue.

PHOTOGRAPHY IN AND OUT OF THE STUDIO

THE PHOTO-ASTRONOMICAL OBSERVATORY AT MEUDON—THE INTENSIFYING OF GELATINE NEGATIVES—PHOTOGRAPHIC ILLUSTRATIONS IN NEWSPAPERS—A SCIENTIFIC SOLDIER.

The Photo-Astronomical Observatory at Meudon.—M. Janssen, the well-known French astronomer, is making the most of his advantages at Meudon. The chateau, which lies a few miles from Paris in a pleasant park, was delivered over—what remained of it after the bombardment by the Prussians—for a photo-astronomical observatory, and M. Janssen, by constant solicitation, has at last induced the French Government to build him a well-constructed observatory. The work has begun in good earnest, but for the winter the operations are suspended, and M. Janssen will have to wait another year before his photo-astronomical laboratory is finished. In the meantime, as we know, M. Janssen has done some good work, and every day, when the sun shines, a series of photographs of the solar disc are obtained. He has an automatic instrument, worked by a weight, which will take six photographs of the sun every twenty-four hours with a nine-inch refractor. We know how rapidly M. Janssen can manage his exposures. He has reduced them to a $\frac{1}{2000}$ of a second, and by this means is enabled to secure something more than a bald solarised disc, resembling a huge white wafer. The curtailment of the exposure prevents detail from being lost, and he has succeeded in securing solar pictures with characteristics which

furnish the groundwork for further astronomical study. Meudon is far more favourably situated than Greenwich as an observatory, for not only is the chateau much more distant from factories and smoke than our own Royal Observatory, but the French metropolis itself gives off far less smoke from its chimneys. Again, there is less chance of fog, which with us is for ever setting over the valley of the Thames, and enveloping Greenwich Hill from top to bottom. But Meudon is not altogether free from thick weather, and just now we hear that M. Janssen has been unable to get a photograph of the sun for days together. His instruments are brought to a standstill, and his staff of assistants are out of work.

The Intensifying of Gelatine Negatives.—Mr. B. J. Edwards' letter, which we published last week, contains full details for intensifying gelatine negatives, and although we cannot admit that it is the only formula in existence which succeeds, we will frankly state that his intensifier acts admirably. We ourselves have tried it on half-a-dozen thin and weak negatives, and transformed these without delay into vigorous plates. In fact, it makes nothing into something. One of the chief difficulties that workers with gelatine plates experience is lack of density, and in the early days many a plate was declared useless which, under treatment of an intensifier such as Mr. B. J. Edwards gives us, rapidly becomes bright and vigorous. For the purpose of experiment, we employed some gelatine plates which had been developed a twelvemonth since, and had been lying neglected and forgotten for the reason that they were too weak and ghostly. They were, after suitable washing, treated in the manner indicated by Mr. Edwards, and within a few minutes transformed, as we have said, into serviceable negatives. Our advice, therefore, is to copy Mr. Edwards' instructions into the laboratory note-book as something well worthy of a place in that record.

Photographic Illustrations in Newspapers.—*Life* continues to present its reader with some excellent pictures, which are stated to be produced by a photo-type process. A large portrait of the Princess of Wales is one of the last, and this is one of the finest productions of the sort that we have seen. There can be little doubt that they are the result of a collographic process of some sort, and the pictures bear a striking resemblance to those early prints that were produced so successfully by Garnier and Tessié du Motay before Albertype and Lichtdruck were heard of. The fact that these fine photographs may be regarded as permanent, while they are certainly the first mechanically-printed portraits of large size that have been issued with a public newspaper, is a matter of singular importance, since we may now be said to have reached a new era in photographic publication. The issue of portraits by the Woodbury process was distinctly a step in this direction, but in this case only portraits of small dimensions were issued with the newspaper, and, moreover, like the ordinary photograph, it was necessary to mount them. The photographs, on the other hand, that are issued with *Life*, and are evidently produced in Paris, are large prints direct from the press, and as stable as the letterpress with which they are issued. They undoubtedly prove that we have made a further step of advancement in photographic illustration.

A Scientific Soldier.—We are glad to hear that the Company of Royal Engineers, or rather Sappers and Miners, as they are still called in India, which General Roberts has with him in Cabul, have the means wherewith to take a series of views of that capital. Although our soldiers have before occupied the Afghan capital and wintered there, we have, strange to say, but little record of its characteristics. A diary that was kept by Lady Sale is well nigh the only trustworthy information that exists on the subject. On the present occasion we have fortunately in our leader, Sir Frederick Roberts, a scientific soldier who is likely to take every advantage of his military position, and will assiduously employ the camera as an aid in surveying, as well as illustrating the characteristics of the country around. It is very

well to talk of a mountainous country and the surmounting of lofty passes, but until we have a picture of them before us we never quite realise the difficulties. General Roberts, to get where he is, had to pass with his artillery and stores over the Shaturgarden a pass 11,000 feet in height, a feat in Europe of which a member of the Alpine Club would feel proud. The photographs in the last Exhibition in Pall Mall, imperfect as they might have been from an art point of view, depict very graphically the difficulties of the road up the Khyber Pass and the craggy height which had to be surmounted before the fortress of Ali Musjid could be stormed. General Roberts will assuredly let us have some photographs of the Bala Hisar, and the city of Cabul, as also of the mountain ranges which command the city on every side. He it was whom we have to thank for the introduction of sunshine signals into the army. The Mance heliograph would never have been at work at Ekowe if General Roberts had not appreciated the advantages of the system. Some six years ago, when he was Quarter-Master-General in Bengal, the Mance instrument was submitted simultaneously to India and the Horse Guards at home. The latter rejected it as impracticable, but General (then Colonel) Roberts ordered half a dozen instruments to be procured, and some Sappers to be at once instructed in their use. It was those instruments, and those Sappers, who afterwards stood the general in good stead in the Kuram Valley, when last year he was in command of that force, and managed by reflected sunshine to maintain telegraphic communication throughout the whole length of the valley. His colleague, Sir Sam Browne, telegraphed the taking of Ali Musjid to Peshawar by a mirror established on the fallen fortress, and we all know how later in Zululand, Colonel Pearson, locked up in Ekowe, was able to communicate in the same way to his chief on the Tugela. The telegraph communication with Cabul, as we know, has recently been cut, but we may be quite sure that before long General Roberts will have established a mirror station on one of the Cabul heights, to communicate with his friends on the Khyber road. Signalling by sunshine has some disadvantages, no doubt, as a system of telegraphy, the necessity for clear weather being one of them; but communication cannot be cut by an enemy, it must be remembered, and this is an invaluable feature of the heliograph.

THE PHOTOGRAPHIC PRIZE.

WHO GAVE IT, WHO WON IT, AND WHAT CAME OF IT.

BY GEO' BRADFORD.

ST. LOE! The romantic name of a very pretty, cosy, and thriving market town in the midland counties; indeed, St. Loe to the full carries out the romance of its name, being, as it is, surrounded by far hills, green fields, and shadowy woods. Numberless are the murmuring rills that brawl around it; while the placid Loe meanders right through its centre, and thus, in its course, having caused at some remote period of the dark ages the erection of that wonderful piece of architecture—the old stone bridge. The latter, with the dilapidated cross in the market place, were the two antiquities of St. Loe. St. Loe, like all other little market towns, might be said to slumber six days out of the week, but on the seventh, when it did wake—the market day—it awoke with a vengeance! From early morn until dewy eve it roared and bustled—hellowed and bartered—it swaggered into booths—it bragged—it blustered and brawled in a manner most unseemly; it let its romance—it lost its poetry, and, in short, would have, in the eyes of a casual observer, appeared to be neither more nor less than a small edition of Sodom and Gomorrah. Nevertheless, as the stars appeared, the rude sounds gradually stopped, and with the faint low of the weary kine on the distant turnpike, or the soft bleat of the huddled sheep on the common, St. Loe returned to its sleepy self, and dozed away for another week amidst its far hills, green fields, and shadowy woods. Only upon two other occasions did St. Loe make an effort at waking up, viz., on its Flower Show and its Cat and Dog Show.

Such a thriving town as St. Loe you may suppose could not be long without a resident photographer; still, so it was; it had had flying visits from gentlemen of the camera, and some-

times its markets were inundated by a few Bohemians who did a roaring trade in glass pictures; but it was only lately that Jenkins took up a permanent abode there. He was a quiet painstaking man—an obliging man—indeed, nothing gave him greater trouble than the thought of any of his customers being dissatisfied; he would have granted sittings for weeks on end, rather than let any one go away grumbling. Now you know this is the proper disposition to succeed if your painstaking and obliging be allied with tact. I am afraid Jenkins was too simple to know even the meaning of the word tact, else why should he have been induced to bestow a photographic prize to the winner of the two-year-old tabby at the St. Loe Cat and Dog Show? I cannot explain to you the circumstances that led Jenkins to take such a step, but it is a melancholy fact that he did it. I believe that his general impression was that it would be a cheap way of advertising, and, of a consequence, increase his business.

As the year drew near its close, the Cat and Dog Show had its day, and towards the close of that said day it was known all through St. Loe that Peter Anketel had won Jenkins' prize by the perfections of his longed-haired, long-tailed Angora cat. Peter Anketel was a tailor, and withal a most extraordinary sort of a fellow. I really don't know but what I should have left the extra out, and said most ordinary fellow, for Peter was ill-made, ill-read, and very badly bred, with a genuine love for nothing except his beer and his cat; and, upon second thoughts, I fancy these are accomplishments belonging to an ordinary fellow.

It was a dull gloomy Monday morning in December that Peter Anketel walked into Jenkins' studio with a pleasant grin on his face, and a small hamper in his hand. After wiping away a drop or two of the last mug that happened to still cling lovingly to his scraggy beard, he exclaimed, "Morning, Mr. Jenkins; I've come after that 'ere prize!"

"Ah, to be sure—to be sure!" quoth Jenkins, cracking his knuckles pleasantly; "you are the winner!"

"No, I bean't!" answered the tailor, bringing his hand with a thump down on the hamper; "but this 'ere cat is!"

"Yes—y-es!" exclaimed Jenkins; "but you know that it is you that is to sit for the photograph!"

"How's that, man?" cried the tailor, looking suspiciously at Jenkins. "Tell'ee I ain't the winner. This 'ere cat is the winner, and it's he as is to be photographed!"

Jenkins tried to explain that it was the owner of the cat, and not the feline itself, that such a prize was meant for; and in his eagerness to eschew the job of having to try such a mad affair as photographing a cat that had been closed up in a hamper for an hour or so, and thumped about until it was nearly wild, and on a black December day, he set to work to wheedle Peter Anketel into sitting himself. When he discovered that Peter was married, as a further inducement he offered to take them both together; but it was all to no purpose.

"Now you just stop your gammon!" roared Peter at length. "You be a stranger in these parts, an' yer not up to our ways. We knows summat up this way, I kin tell ye. If a horse wins a race, it be the horse that wins, and not the measter; an' if a cat win a prize, why don't ye, gie the cat the prize, an' ha'e done wi' it. Is yer doors an' winders shut?—because she's kind o' wild when she fust gets out. Now then my boo-ty!"

And with these words, he opened the hamper, and, with a snarl, out bounded the great cat and commenced to inspect and smell the furniture.

"Haint sho a boo-ty?" cried the tailor, gazing at her admiringly. "And look here, sir, I wants her took stood up!"

Jenkins sighed, and went into his dark room, vowing that he would take better care of the wording of the next prize he gave. Jenkins brought all his patience to bear upon the absurd case. He at first tried to make friends with the cat, but hastily abstained upon seeing her lay back her ears and show her teeth.

"Nae, thee mustn't do that; she have a nasty way wi' strangers," warned Peter.

Fifteen times did Jenkins try that cat, and fifteen times Jenkins failed! What Jenkins said when he was in the dark room I do not know, but it was not poetry. At length his patience came to an end. With tears in his eyes he addressed Anketel, who, to make matters worse, sat smoking, thus filling the little glass room with additional fog.

"My dear sir, it is a moral impossibility for me or any one to photograph that cat; but I am a man of peace, and I am willing to photograph you and your family—your grandfather and your grandmother, your uncles, aunts, brothers, sisters, cousins, your children, your grandchildren—in fact, all your royal family, in one immense group as an equivalent. Is it a bargain?"

"Dang it all!" quoth the tailor, scratching his head, "it's a fair offer; but—*jest try the cat again*, will ye, and I'll do my best to keep her still?"

Jenkins groaned, but, Job-like, tried another plato. He whistled at the cat, he roared, he screamed, he clashed the lid of the fire stove; he sprang into the air, and came down yelling—he got excited! This excitement was evidently contagious, for Peter Anketel so far forgot himself as to give Mrs. Angora a good cuff. That cuff put a stop to the whole proceedings, for Mrs. Puss, in an awful state of excitement herself, and totally bewildered by the unearthly sounds, snapped at her master, and inflicted a sharp bite on the forefinger of his left hand. Jenkins' shouts had a joyful ring in them when he perceived the blood Sanguinary wretch! He saw that his hour of triumph had arrived.

"A most dangerous thing to be bitten by a cat," quoth he, grimly. "I have known of several awful deaths through such. The only preventive is the death of the cat. Of course, you can please yourself; but if I were in your place, I would not rest until I had destroyed that cat!"

Loudly laughed the tailor as he scornfully waved his gory hand, and exclaimed: "Tell'ee what—yer a duffer. I'll bet the neebours know what sort o' man you are. I'll show 'em what sort o' photographer yer are! Yer a duffer!"

And with a good many worse expressions than these, Peter Anketel, the tailor, stuffed his cat into his hamper, then, with one withering look, walked away straight to the top of the Three Bells. Jenkins watched him disappear under the archway, then muttered: "Duffer? By Heavens! but I shall be revenged on that fellow—I shall not rest until he has drowned his cat!"

How Jenkins managed his part I am about to tell: the means he used you can easily guess it. Hardly had Peter Anketel commenced his sentiments regarding the prize and Jenkins to a gaping audience of loafers, than the landlady casually remarked—

"What is the matter with your hand, Peter?"

"Cat bit it when I was trying to hold him for that fool!"

"Cat drowned?"

Peter laughed, but not quite so heartily or so scornfully as he had done in Jenkins' glass room. And now the landlady retailed a few harrowing instances of deaths resulting from such bites, some of which brought queer, creeping sensations up and down the small of Peter's back. However, Peter shrugged his shoulders, and in a loud voice called for more beer. In vain Peter tried to turn the conversation. If for a short time his abuse of Jenkins was overpowering, so that the company could not even get a word slipped in edgeways, still the flood of his eloquence was sure to come upon the final denouement and the bite. Or if politics claimed the company's attention, so that the prize and the cat and the bite were all forgotten, it was singular—in fact, one of those singular occurrences that are remembered even until this day in the annals of St. Loe gossip—it was singular, I say, that some one was sure to drop in and remark the two bloody punctures on Peter Anketel's forefinger. Then followed the unvarying question: "Cat drowned?"

This constant dropping began to have its effect. Peter no longer laughed, and ultimately he did not wait for acquaintances to observe the marks by chance, but showed them to them, and in a mysterious whisper asked their opinion. Then, of course, came that unvarying verdict—Drown the cat!

It was likewise a singular thing on that eventful day that Jenkins, the peaceable, the patient, was strangely excited; and it was remarked that his face was often seen glued to the smoky window of the bar-tap, and that it wore a fiendish grin.

Through the ale and the horrible tales that he imbibed, Peter's imagination became so excited that he felt sure he was suffering from the earlier symptoms of approaching dissolution. So he drank and talked hydrophobia until evening, when he resolved, as a final test, to appeal to the common sense of his good friend Mendem, the shoemaker, and abide by his decision. If he said with the others, he would have that cat's life that very night, or perish in the attempt. Full of ale and trouble, Peter at length arose to seek his friend. Now it was cruel of someone hidden in a door-way, to cry mew-mew as he passed! The cry made his hair stand on end, and he well nigh burst into tears as he thought on the depravity of human nature, that it could so indulge itself at the expense of a fellow-creature whose life was, so to speak, hanging in the balance. When Peter had told his now lengthy story to the shoemaker, the latter, whose

face had remained immovable during the recital, albeit Peter tried his hardest to make his position as tragic as possible, arose slowly from his seat, and whistling softly to himself, reached down a country paper, and pointing to a paragraph with his forefinger, handed it to Peter.

Peter tremblingly read the title, "Horrible death from the bite of a cat!" What Peter did or said, I cannot exactly tell, but perhaps the sequel will show.

The moon was shining peacefully down upon the lazy Loe and its old stoue bridge, when a man stepped forth from a gloomy doorway; his movements were stealthy, and he bore beneath his arm a bundle—a mysterious bundle from whence proceeded strange smothered noises. The long High Street of St. Loe was deserted, the lights had all but disappeared from the windows of the dwellers, and nothing was heard but the slow and solemn tread of the watchman as he paced his weary round. With a precaution that betokened guilt did that wretched man proceed towards the brink of silent running Loe.

Nearer and nearer! There was no mistaking the wretch's truculent manner. He was bent upon crime.

He now stood on the brink. A sudden motion—a heave and a splash!

Simultaneous with the splash a man very like Jenkins jumped up from behind the buttress of the bridge, and shouted, "Help! Help! Someone drowning!"

And he who had done the deed, fled—fled as swift as the wind, and in his headlong career overturned the guardian of the night, who, seeing a man running as if for life, concluded that he had at least committed murder; so instantly gaining his feet he made after him with all speed. He was a big policeman, and the sound of his feet made an awful noise in the silent streets. People heard and wondered—jumped out of bed—threw open the windows—and, spying the excited chase, sprang into what clothes they could lay their hands on, and followed suit.

It is a well-known fact that there is nothing easier to be obtained than a crowd; and in this instance the man who had disposed of the mysterious bag in the silent waters of the Loe found himself the leader of as motley a crowd as was Falstaff's regiment. He doubled his speed, and flew rather than ran. So well did he succeed, that he dashed into the dark doorway from whence he had so lately emerged before the foremost of them had turned the corner. Before they had arrived, he had double-locked the door, and was eyeing them cautiously from the corner of the first floor window.

"Where the devil has he got to?" asked a man who was easily distinguished by having nothing on but a shirt and an ulster.

"Lord knows!" gasped the policeman.

"What did he do?" again asked the ulster and shirt.

"Lord knows!" again gasped the policeman.

"What on earth did you chase him for, then?" yelled the excited mob.

"Because he ran like the devil!" replied the policeman.

And Jenkins, the photographer, went to bed chuckling that night, and did not even tell his wife until next morning.

The next day happened to be fine, clear, and frosty, so that Jenkins expected to do a little trade. Towards noon, who walks into his studio but Peter Anketel, with his Sunday coat on?

"Look here, Mister!" he exclaimed; "I've changed my mind about that 'ere prize. I've come to be took myself."

"Sorry to say," replied Jenkins the painstaking and obliging, in firm accents, "that I have changed my mind, too, and I am determined that I shall only photograph the cat. So go and fetch it!"

Anketel slunk towards the door muttering.

"How is the bite?" quoth Jenkins. "Feel any bad effects—eh?"

"Oh, don't thee and thy prize too!" roared the exasperated tailor, as he rushed off in a rage.

And then Jenkins, the painstaking and obliging, went up and down in St. Loe, and told the inhabitants all about his prize—who gave it—who won it—and what came of it.

GERMAN PYROGALLIC ACID.

In a recent issue of the PHOTOGRAPHIC NEWS we published a letter from Mr. Fry, in which he expressed a conviction that thinness in gelatine negatives was often the result of using German pyrogallie acid. Messrs. Schering, of Berlin, regarding this as a personal allusion, have submitted a

sample of their pyrogallie acid, together with an English sample, to Dr. Vogel for comparison. He has sent us the following statement of results.

Two kinds of pyrogallie acid were handed to me, the one from the chemical manufactory (on shares) of E. Schering, the other from the manufactory of—*, in London. I was also informed that a London examination had shown the English pyrogallie acid to possess towards bromide of silver a power of reduction far greater than that of the German acid. How they had been tested with reference to bromide of silver is not stated; I therefore wish to make a few introductory remarks.

Bromide of silver can be reduced by pyrogallie acid only in the presence of alkalis, and the intensity of the reduction increases in the same proportion as the quantity of alkali present, the concentration of the solution, and the influence of light are increased.

Hence, if two quantities of pyrogallie acid were to be tested as to their respective powers of reduction, not only the weight of the pyrogallie acid, but also that of the ammonia (or alkali), and the degree of concentration have to be exactly equal in each case; moreover, the influence of light, as far as possible, has to be excluded, otherwise considerable sources of error will be created. On the other hand, pyrogallie acid in the presence of alkalis is also oxidized by the oxygen of the air. If, therefore, pyrogallie acid be tested in the presence of air, the latter will destroy by oxidation a portion of the acid, which will increase in the same proportion as the quantity of air present. Hence, in the operations of testing, differences will arise even from the employment of vessels of unequal size.

In order to avoid all these sources of error, I proceeded as follows:—

I took two bottles of yellow glass which excluded such rays of light as might have caused a chemical change, both holding 200 cub. cents. Into each bottle I poured exactly 8.5 cub. cents. of a solution of nitrate of silver which contained 1.2 grammes of nitrate of silver. To this were added 6 cub. cents. of bromide ammonia solution. It had been previously ascertained that 5.9 cub. cents. of the said bromide of ammonia solution were capable of precipitating the above mentioned argentic nitrate solution. Hence the bromide of ammonia remained a trifle in excess—that is to say, to an equal amount in the two testing liquors. Then to each of the two testing liquors 2 cub. cents. of ammonia were added, and, exactly at the same time, to one of them a solution of 1 gram of Schering's pyrogallie acid, in 10 cub. cents. of alcohol; to the other a solution of 1 gram of English pyrogallie acid in 10 cub. cents. of alcohol. Both were afterwards, during the space of ten minutes, contemporaneously and uniformly shaken in a closed bottle. Then each liquid was emptied into a glass containing sulphuric acid in sufficient quantity to saturate the given amount of ammonia. By means of this acid the ammonia was at once neutralized, and thereby the reducing power of the pyrogallie acid upon bromide of silver instantaneously checked. Each of the amounts of bromide of silver thus treated was then brought upon a filter and carefully washed out, then both the filters, together with the precipitates, placed into glass vessels, where diluted nitric acid (sp. gr. 1.1) was poured upon them.

It has previously been established that the diluted acid on being heated does not attack the bromide of silver, but nearly solves the admixture of silver produced by reduction.

Through application of heat, this solving of the reduced silver was in both cases effected, and then its amount determined by trituration with a solution of potassic iodide according to a well-known method of silver trituration. With the English acid I obtained 896 grams, with Schering's 937 grams of argentic nitrate solved.

The result shows that under identical circumstances the reducing capacity of Schering's pyrogallie acid is considerably greater than that of the English acid, and from

* The name of a highly respectable firm of manufacturing chemists is here given.—Ed.

the mentioned results it follows that the English pyrogallie acid reduced $74\frac{3}{4}$ per cent., Schering's $78\frac{1}{2}$ per cent. of the argentic bromide employed. If, therefore, it be asserted that the English pyrogallie acid possesses greater reducing power than that of Schering, the assertion is, in my opinion, an erroneous one caused by errors in testing. Had the English pyrogallie acid really greater powers of reduction than Schering's it would show itself in the most conclusive manner when gelatine dry plates are being developed. But if a dry plate be exposed in the stereo apparatus, cut into two, then one half brought out with Schering's, the other with English pyrogallie acid, while exactly the same amounts of potass bromide, water, and ammonia are added, a superior effect of the English pyrogallie acid is not in the least perceptible. Both halves are brought out with equal speed and intensity, a fact which proves that in employing very small quantities of ammonia (as is usual in bringing out dry negatives) the difference of the reducing capacities, as shown in the above described quantitative testing, is not so conspicuous. I must likewise oppose the assertion that the pictures developed with English pyrogallie acid are more intensely black than those produced with Schering's pyrogallie acid. If one proceeds under circumstances exactly alike, the intensity of the negatives obtained must also be the same.

This I certify truthfully,

(Signed) PROFESSOR DR. J. VOGEL.

Berlin, 4th November, 1879.

[It is scarcely necessary to point out here that no name of any German chemical manufacturer was mentioned in Mr. Fry's letter, and unless Messrs. Schering are the sole manufacturers of pyrogallie acid in Germany, they were not necessarily implicated in the imputed charge. We have pleasure, however, in giving publicity to Dr. Vogel's interesting results. It should be remembered in all operations with pyrogallie acid that its age and conditions are important factors in its activity. An old sample which has had some exposure to the atmosphere loses much of its reducing power.—Ed.]

ART AND ITS RELATION TO PHOTOGRAPHY.

A SERIES OF PAPERS.

No. III.

BY AN ART STUDENT.

BEFORE commencing a portrait, it is essential, then, that the line upon which it is based is clearly mapped out in the artist's mind;—for to commence a picture without any definite object in view; to place the model and reproduce it, giving prominence and importance to those points which ought to be subordinate; to pose it without having thoroughly fixed the particular place of feeling you wish to throw into the face; to arrange the draperies and the body with hardly any knowledge of the forms that body takes without its covering;—to begin work under these disadvantages must inevitably result in failure. If we examine the works of the great masters, it will be found that there is an underlying current, so to speak, throughout all their compositions—a key, or high note, which governs their work in the same way that the leader of an orchestra gives the note whereby the rest are enabled to play in unison. Without this starting point there would be bound to be a great amount of discord; and in the same manner, without this note or starting point, all art work would contain discordant parts. The object, then, is to find the key to the composition, and to arrange it accordingly. If it is repose, let repose pervade the picture, and *vice versa*. And here I would add, there is necessarily a limit beyond which it is inadvisable to attempt to go. No matter how high the artist's imagination may soar—it may be a most lofty and noble conception—yet if unsuitable for pictorial display, or unattainable, *there is nothing to show*, or the effort,

being beyond the capabilities, ends in the ridiculous or repulsive. Whenever this happens, although the result may be *nil*, a lesson has been taught and fault guarded against for the future. At present there are samples of photographic failures to be seen daily in the London shop windows. One in particular is that of a well-known and able actor, who is represented as in the last stage of *delirium tremens*. The aim has been high so far, but the attempt an undoubted failure, descending to the level of the absurd, for the simple reason that it is quite unsuitable. There is none of this absurdity to be found in the actor on the stage, however; here we have the repulsive as a contrast; not but what the representation of the actor is true and life-like, but the fault lies in the fact that such an imitation, no matter how true it be, is only fit for those whose taste is for the morbid, and quite unsuitable to be the subject of a pictorial composition. It is one which no cultivated person could delight in.

Art has for its object the elevation of our species, and no good can ever come of accustoming our eyes to dwell upon scenes of horror. Such a theme as a man in the last throes of a hideous disease can never rise to the sublime; and if attempted to be reproduced in a picture by any other than a master's hand, it is bound to partake of the ridiculous; and as either is objectionable, it were better that such effort should be left alone. True, Hogarth, in the "Rake's Progress," introduces us to the interior of a mad-house; yet look how he has counterbalanced the dreadful parts of the picture—the women lovingly tending and soothing the poor lunatic, while the repulsive feeling with which we might be inclined to view the others is taken away when we perceive how little they feel their position—how the possession of a few trumpery playthings has the effect of keeping them employed and alleviating their misery. To depict facial expression—to give grace and dignity to the carriage of the figure—to cause the eye to dwell upon those points on which it is intended it should dwell, are some among the many difficulties which it is essential the artist should try to surmount. In painting there are many methods of obtaining the relief, and consequently the importance, which is due to the head. Rembrandt's style is one of the most masterly. By throwing the entire figure into shade, he thus obtains and concentrates the light upon the face; but there is not a particle of cutting line to be found. Unlike the photographic Rembrandt—which has usually one-half of the face a patch of unbroken white against a dark background—everything is softened away. The light plays upon the projecting points of the mask, throwing them forward; from thence the gloom and shadow slowly gather. There is no want of roundness, however, in the deepest parts—no lack of detail: if we look for it, it is there, but does not thrust itself on the eye. The head of a Capuchin Monk, in the National Gallery, Trafalgar Square, is well worthy of a careful study, showing, as it does, how it is possible to combine high lights and deep shadows, the details fully wrought out in each, yet subservient to the whole, and the head looming grandly forth, and rivetting the entire attention.

Correspondence.

INTENSIFYING GELATINE NEGATIVES.

DEAR SIR,—I believe the formula for intensifying gelatine negatives by the modified method of mercury iodide was given by Mr. B. J. Edwards to the public, and he is most certainly in error by stating that I described it as my own. The formula I gave was that which worked best with me, and I defy Mr. Edwards to prove that the formula I gave is anything but correct. I tried the formula given by Mr. Edwards a short time since in another journal, and after carefully carrying out the directions there given, I managed

to spoil three pints of solution; so I set to work, and began with 60 grains of bichloride of mercury dissolved in 4 ounces of distilled water; then I dissolved 110 grains of potassium iodide, and added, which did not quite dissolve the red iodide of mercury that was formed, so by adding 10 grains at a time I just obtained what Mr. Edwards had described, *i.e.*, that the red precipitate should be nearly dissolved; 140 grains of iodide of potassium gave this result; then by adding 40 grains of hypo dissolved in 2 ounces of water (and not, as Mr. Edwards gave it, put the crystals into the solution) I found that it gave a clear solution; and whether correct or not in Mr. Edwards's estimation, it did intensify several weak gelatine negatives to perfection; and thus, having found the proportion that gave me the best results, I published it for the benefit of others; and further than this, it now forms a part of the instructions sent out with my gelatine plates.

Undoubtedly, the hypo-mercurial intensifier is due to Mr. Edwards, but I do think that he has no occasion whatever (having made it public) to snap at any other person for making a modification of it to suit a desired end.—Very truly yours,
A. J. JARMAN.

41, Queen Street, Ramsgate.

Proceedings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society took place at the Memorial Hall, on Thursday, the 11th inst., Mr. ALFRED BROTHERS, F.R.A.S., Vice-president, in the chair.

After the minutes of the previous meeting were read and confirmed, Mr. J. C. Hathersley was duly elected a member of the Society.

Mr. JOHN SCHOLFIELD then presented to the Society a developing tray or box made of metal constructed to form a sink as well as a chemical chest, and a special vote of thanks was awarded to him for his very handsome present.

Mr. PARKINSON, of Bolton, at the request of the Chairman, promised, if possible, to bring to the next meeting a print or enlargement from a negative he had succeeded in taking, by the aid of the electric light, of a large group—the Choral Society of Bolton, and which has been noticed in the photographic journals.

Mr. GEORGE GREGORY then read paper a entitled "Artistic Photography."

Mr. S. W. LEIGH exhibited some very excellent photographs from 11 by 9 negatives printed upon unglazed drawing paper, and also the very handsome prize he had been awarded by the Amateur Photographic Association, and a print from his prize negative.

Mr. J. POLLITT explained that he had produced many prints on paper only slightly albumenized, which rendered them very effective for working upon afterwards, and notwithstanding the result was similar to those exhibited by Mr. Leigh, they were printed in much less time.

Mr. W. WATTS then read a paper entitled "Electro-Depositions in Connection with Photographs," and afterwards conducted some very interesting experiments, projecting the same on the screen by means of the lime light spectrogon, and exhibited very beautiful specimens of electro-depositions.

A vote of thanks was then passed to Messrs. Gregory, Watts, Leigh, and the Chairman, after which the meeting adjourned.

PHOTOGRAPHIC SOCIETY OF IRELAND.

THE usual monthly meeting of this Society was held in the Royal College of Science on the 12th inst., Mr. GEORGE MANSFIELD in the chair.

The minutes of the previous meeting having been read and confirmed,

Mr. COWAN showed in detail the preparation of gelatine emulsion, going through the actual process at each stage. This was done with a view of encouraging amateurs to prepare their own plates, and, by demonstrating the simplicity of doing so, remove the objection which is generally entertained. Three new members having been proposed for election, the meeting adjourned, after having inspected the collection of prints from which the presentation print to be issued by the Society was recently selected.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The first meeting for the Session 1880 will take place on Thursday next, Jan. 1st, in the large room of the Society of Arts, Adelphi, when the evening will be devoted to a lantern exhibition for the display of members' slides and others, after which Messrs. W. Brookes and F. A. Bridge (who will superintend the proceedings) will continue the entertainment. Tickets may be had of the Secretary, H. Garrett Cocking, High Road, Lee, S.E.

THE RIGHT HON. W. E. GLADSTONE.—As the Right Hon. W. E. Gladstone completes his 70th year on the 29th inst., about thirty of the leading Liberals of Lincoln have subscribed for a handsome birthday present for the right hon. gentleman, in response to an invitation from the Mayor. The gift is to take the form of fifty of the finest photographs of Roman, early Norman, Gothic, and mediæval architecture in Lincoln, which have been purchased and mounted, and will be handsomely bound in morocco. The first page will contain the dedication to Mr. Gladstone, to be followed by the signatures of the Mayor, the Sheriff, and others. It will be forwarded to Haverden Castle so as to reach Mr. Gladstone on his birthday.

To Correspondents.

R. W.—There is no lack of photographic colourists; the profession is, in fact, somewhat crowded. But the really skilful are generally in demand, and are kept fully employed; they are not very numerous. The wisdom of training a young person to such a profession depends entirely on circumstances, such as capacity, probability of having a connection, &c.

J. K.—To secure good collodion enlargements on opal requires some experience. The collodion should be tolerably ripe, and the bath in good condition. A pyrogallic acid developer is desirable: 2 grains of pyro, 30 minims of acetic acid, and 1 ounce of water will answer. A tolerably full exposure and rapid development will give you the warmest tones. A solution of chlorido of gold containing two grains in an ounce of water, neutralized by means of prepared chalk, will give a rich black tone; continue the application of the gold solution until the image appears the same at the back as the front. 2. We believe no license is required for the use of the double transfer process. Certainly none is required for enlarging.

MR. W. CRISP, of Chester-le-Street, writes to mention the very fine and rapid results he had seen produced on some gelatine plates prepared by Mr. Clennett, of West Hartlepool. It is very gratifying to hear of such satisfactory results on the plates prepared by a gentleman who has only recently commenced their commercial manufacture.

STEAM BURNISHER.—It was made to order. Mr. Calder's address is 179, Maxey Road, Plumstead.

F. HENLEY.—To make the emulsion into a pellicle, pour it out into a dish, so as not to exceed a quarter of an inch deep of the emulsion. Then allow it to dry. When nearly dry, cut it into strips; and when quite dry they will curl up from the dish in the form of pellicle. 2. Imperfect washing will leave an unnecessary salt present, a nitrate of cadmium or ammonium, or whatever base was in the bromide. 3. We have never measured the quantity necessary to coat a quarter-plate, but we have no doubt that the Doctor is right. Yes, 10 cub. cents. are equivalent to 2½ drachms.

S. B. M.—The reticulation you describe is very distressing, and there is, we fear, no cure for it. The best plan is to mix off the collodion with a newer sample which does not reticulate. You will often find such collodion very useful for mixing with a new unripe sample which tends to work thin and foggy.

W. J. CHAPMAN.—Yes, your statement of the case is correct. The chief novelty in the case in question is the arrangement for portability and packing.

G. L. M.—The distorted negative of which you send us a print is due to attempting to hasten the drying of the negative by heat. Gelatine, if it contain any moisture, will generally melt when brought into contact with heat, and if a film in any degree melt it is certain to run a little, and hence the distortion. The negative must dry spontaneously. This may be aided by a drying-box, or by keeping them in a room where there is a current of air.

A. L. E. D.—The price of the PHOTOGRAPHIC NEWS by post is 15s. per year, or 3s. 10d. per quarter payable in advance. The order should be sent to the publisher. To print on linen, sponge or soak it with a solution of five grains of common salt in an ounce of water. When dry, apply a 30-grain solution of nitrate of silver, dry, and print. Then fix and wash as usual. The price of the YEAR-BOOK is 1s., and 2d. postage.

J. C. STEPHENS.—YEAR-BOOK copy received. Thanks. We will write.
